WMO-No. 168

EDITORIAL NOTE

The following typographical practice has been followed: Standard practices and procedures have been printed in **bold**. Recommended practices and procedures have been printed in regular font. Notes have been printed in smaller type.

METEOTERM, the WMO terminology database, may be consulted at <http://public.wmo.int/en/resources/meteoterm>.

Readers who copy hyperlinks by selecting them in the text should be aware that additional spaces may appear immediately following <http://>, <https://>, <ftp://>, <mailto:>, and after slashes (/), dashes (-), periods (.) and unbroken sequences of characters (letters and numbers). These spaces should be removed from the pasted URL. The correct URL is displayed when hovering over the link or when clicking on the link and then copying it from the browser.

PREFACE	xiii
ACKNOWLEDGEMENTS	xv
CHAPTER 1. INTRODUCTION	I.1-1
1.1 Background	I.1-1
1.2 Scope	I.1-1
1.3 Contents of the Guide	I.1-2
1.4 The Hydrological Operational Multipurpose System	I.1-4
References and further reading	I.1-4
CHAPTER 2. METHODS OF OBSERVATION	I.2-1
2.1 Introduction – The hydrological cycle as the subject of observation	I.2-1
2.2 Water resources information systems	I.2-2
2.2.1 Need for data and information	I.2-2
2.2.2 Hydrological information systems	I.2-3
2.2.3 Uses of water resources information	I.2-5
2.2.4 Types of water resources information	I.2-5
2.3 Hydrological symbols, codes and accuracy of measurements	I.2-7
2.3.1 Units and symbols	I.2-7
2.3.2 Hydrological codes	I.2-7
2.3.3 Accuracy of hydrological measurements	I.2-12
2.3.4 Calibration of instruments	I.2-17
2.4 Design and evaluation of hydrological networks	I.2-18
2.4.1 General concepts of network design	I.2-18
2.4.2 Density of stations for a network	I.2-24
2.4.3 Specific requirements for water quality	I.2-28
2.4.4 Operational data acquisition networks	I.2-34
2.4.5 Network-strategy options	I.2-34
2.5 Data collection	I.2-35
2.5.1 Site selection	I.2-35
2.5.2 Station identification.....	I.2-35
2.5.3 Frequency and timing of station visits	I.2-39
2.5.4 Maintenance of sites	I.2-40
2.5.5 Observation	I.2-40
2.5.6 Transmission systems	I.2-43
2.5.7 Water-quality monitoring	I.2-44
2.5.8 Special data collection	I.2-46
2.6 Measurement of physiographic characteristics	I.2-47
2.6.1 General	I.2-47
2.6.2 Reference systems and data frameworks	I.2-47
2.6.3 Point measurements	I.2-48
2.6.4 Linear measurements	I.2-49
2.6.5 Area measurements	I.2-52
2.6.6 Volumetric measurements	I.2-55
2.6.7 Geographical Information Systems	I.2-55
2.6.8 Emerging technologies	I.2-56
2.6.9 Staff training	I.2-57
References and further reading	I.2-58

CHAPTER 3. PRECIPITATION MEASUREMENT	I.3-1
3.1 General requirements: accuracy and precision	I.3-1
3.2 Raingauge location	I.3-1
3.3 Non-recording raingauges	I.3-3
3.3.1 General	I.3-3
3.3.2 Standard raingauges	I.3-3
3.3.3 Storage raingauges	I.3-3
3.3.4 Methods of measurement	I.3-4
3.3.5 Errors and accuracy of readings	I.3-4
3.3.6 Correction of systematic errors	I.3-5
3.4 Recording raingauges	I.3-7
3.4.1 Weighing-recording gauge	I.3-7
3.4.2 Float gauge	I.3-7
3.4.3 Tipping-bucket gauge	I.3-8
3.4.4 Rainfall-intensity recorder	I.3-8
3.4.5 Distrometers	I.3-8
3.4.6 Acoustic type	I.3-9
3.4.7 Methods of recording the data	I.3-9
3.5 Snowfall and hail	I.3-9
3.5.1 Depth of snowfall	I.3-9
3.5.2 Water equivalent of snowfall	I.3-10
3.5.3 Snow cover	I.3-10
3.5.4 Hail pads	I.3-15
3.6 Rainfall estimation from catchment water balance	I.3-15
3.7 Observation of precipitation by radar	I.3-15
3.7.1 Uses of radar in hydrology	I.3-15
3.7.2 The radar–rainfall equation	I.3-15
3.7.3 Factors affecting measurements	I.3-16
3.7.4 Snow and hail	I.3-18
3.7.5 Scanning strategy	I.3-19
3.7.6 Summary of accuracy considerations	I.3-19
3.7.7 Doppler radar	I.3-19
3.7.8 Multi-parameter radar	I.3-20
3.8 Ground-based radar and rainfall monitoring techniques	I.3-20
3.9 Operational radar networks	I.3-21
3.10 Dual frequency microwave link attenuation measurements of rainfall	I.3-21
3.11 Observations of rainfall by satellite	I.3-22
3.11.1 Basics	I.3-22
3.11.2 Visible and infra-red	I.3-22
3.11.3 Passive microwave	I.3-23
3.11.4 Active microwave (rain radar; Tropical Rainfall Measurement Mission)	I.3-24
3.11.5 Summary of accuracy considerations	I.3-25
3.12 Remote-sensing measurements of snow	I.3-25
3.13 Satellite remote-sensing of snow cover	I.3-26
3.14 Operational satellites	I.3-27
3.15 Dew	I.3-28
3.16 Sampling for precipitation quality	I.3-29
3.16.1 Rain and snow collectors	I.3-29
3.16.2 Dry deposition collection	I.3-29
3.17 Assimilation of rainfall into hydrological and hydraulic models: combining and assessing data from different sources	I.3-29
3.18 Global Precipitation Climatology Project	I.3-30
References and further reading	I.3-30

CHAPTER 4. EVAPORATION, EVAPOTRANSPIRATION AND SOIL MOISTURE	I.4-1
4.1 Evaporation, evapotranspiration and interception.....	I.4-1
4.1.1 General	I.4-1
4.1.2 Definitions	I.4-1
4.1.3 Measurement of evaporation	I.4-2
4.1.4 Measurement of evapotranspiration	I.4-6
4.1.5 Remote-sensing measurements of evaporation and evapotranspiration variables ..	I.4-7
4.2 Estimating evaporation from free surfaces	I.4-8
4.2.1 General	I.4-8
4.2.2 Water budget	I.4-8
4.2.3 Energy budget	I.4-8
4.2.4 Mass-transfer method	I.4-10
4.2.5 Combination of aerodynamic and energy-balance methods	I.4-11
4.2.6 Extrapolation from pan measurements	I.4-12
4.2.7 Empirical formulae	I.4-14
4.3 Evapotranspiration from drainage basins	I.4-16
4.3.1 General	I.4-16
4.3.2 Water-budget method	I.4-17
4.3.3 Energy-budget method	I.4-17
4.3.4 Aerodynamic approach	I.4-18
4.3.5 Penman–Monteith method	I.4-18
4.3.6 Priestley–Taylor (radiation) method	I.4-19
4.3.7 Complementary method	I.4-19
4.3.8 Crop coefficient and reference evapotranspiration method	I.4-20
4.3.9 Large aperture scintillometer	I.4-20
4.4 Evaporation reduction	I.4-20
4.4.1 From free surfaces	I.4-20
4.4.2 From soil surface	I.4-21
4.5 Soil moisture measurement	I.4-21
4.5.1 General	I.4-21
4.5.2 Quantitative methods	I.4-22
4.5.3 Qualitative methods	I.4-28
4.5.4 Remote-sensing	I.4-29
References and further reading	I.4-30
CHAPTER 5. SURFACE WATER QUANTITY AND SEDIMENT MEASUREMENT	I.5.1
5.1 Water levels of rivers, lakes and reservoirs	I.5-1
5.1.1 General	I.5-1
5.1.2 Gauges for measurement of stage	I.5-1
5.1.3 Procedures for measurement of stage	I.5-2
5.1.4 Frequency of stage measurement	I.5-2
5.2 Ice on rivers, lakes and reservoirs	I.5-3
5.2.1 General	I.5-3
5.2.2 Elements of ice regime	I.5-3
5.2.3 Methods of observation	I.5-3
5.2.4 Times and frequency of observations	I.5-3
5.2.5 Accuracy of measurement	I.5-4
5.3 Discharge measurements and computation	I.5-4
5.3.1 General	I.5-4
5.3.2 Measurement of discharge by current meters	I.5-4
5.3.3 Measurement of discharge by the float method	I.5-9
5.3.4 Measurement of discharge by dilution methods	I.5-10
5.3.5 Computations of discharge by indirect methods	I.5-11

	<i>Page</i>
5.3.6 Measurement of discharge under difficult conditions	I.5-12
5.3.7 Non-traditional methods of stream gauging	I.5-16
5.4 Stream-gauging stations	I.5-21
5.4.1 Purpose of stream-gauging stations	I.5-21
5.4.2 Selection of site	I.5-21
5.4.3 Stage-discharge controls	I.5-22
5.4.4 Measuring structures	I.5-23
5.4.5 Stage-discharge relationships	I.5-23
5.4.6 Computation of mean gauge height of a discharge measurement	I.5-25
5.5 Sediment discharge and yield	I.5-25
5.5.1 General	I.5-25
5.5.2 Selection of site	I.5-25
5.5.3 Measurement of suspended-sediment discharge	I.5-25
5.5.4 Measurement of bed-material discharge	I.5-27
References and further reading	I.5-29
CHAPTER 6. GROUNDWATER	I.6-1
6.1 General	I.6-1
6.2 Occurrence of groundwater	I.6-1
6.2.1 Water-bearing geological units	I.6-1
6.2.2 Development of a hydrogeologic framework	I.6-2
6.3 Observation wells	I.6-5
6.3.1 Installation of observation wells	I.6-5
6.3.2 Testing of observation wells	I.6-11
6.3.3 Sealing and filling of abandoned wells	I.6-11
6.4 Groundwater-level measurements and observation well networks	I.6-11
6.4.1 Instruments and methods of observation	I.6-11
6.5 Aquifer and confining-bed hydraulic properties	I.6-18
6.5.1 Hydraulic parameters	I.6-18
6.5.2 Overview of common field methods to determine hydraulic parameters	I.6-20
6.6 Recharge and discharge, sources and sinks in a groundwater system	I.6-21
6.6.1 Recharge from precipitation	I.6-22
6.6.2 Groundwater–surface water relationships	I.6-22
6.6.3 Well pumpage	I.6-23
6.7 Use of data in groundwater models	I.6-23
6.8 Remote-sensing	I.6-23
References and further reading	I.6-24
CHAPTER 7. WATER QUALITY AND AQUATIC ECOSYSTEMS	I.7-1
7.1 General	I.7-1
7.2 Specific requirements for water-quality monitoring	I.7-1
7.2.1 Water-quality parameters	I.7-1
7.2.2 Surface-water quality	I.7-1
7.2.3 Precipitation quality	I.7-3
7.2.4 Groundwater quality	I.7-4
7.2.5 Sediment quality	I.7-5
7.3 Sampling methods	I.7-5
7.3.1 Types of water samples	I.7-6
7.3.2 Collecting a representative water sample	I.7-6
7.3.3 Sampling for the analysis of water stable isotopes	I.7-6
7.3.4 Radioactivity measurement	I.7-7
7.3.5 Field sampling equipment and techniques	I.7-7

	<i>Page</i>
7.4 Preparation for field trips	I.7-10
7.4.1 General preparation	I.7-10
7.4.2 Selection of sample volumes	I.7-10
7.4.3 Checklist prior to field trip	I.7-10
7.5 Field measurements	I.7-10
7.5.1 Automatic monitoring	I.7-10
7.5.2 Field-measured parameters	I.7-10
7.6 Biomonitoring and sampling for biological analysis	I.7-13
7.6.1 Microbogical analysis	I.7-14
7.6.2 Macrobiota	I.7-15
7.6.3 Biochemical oxygen demand	I.7-15
7.7 Field filtration and preservation procedures	I.7-17
7.7.1 Filtration	I.7-17
7.7.2 Preservation techniques	I.7-18
7.8 Remote-sensing and surface-quality water	I.7-19
7.8.1 Water-quality study in the visible and infra-red domain	I.7-19
7.8.2 Water-quality study in the microwave domain	I.7-20
References and further reading	I.7-20
CHAPTER 8. SAFETY CONSIDERATIONS IN HYDROMETRY	I.8-1
8.1 General practices	I.8-1
8.2 Safety at recording stations	I.8-1
8.2.1 Access	I.8-1
8.2.2 Platforms	I.8-1
8.2.3 Wells	I.8-1
8.3 Safety precautions when working from bridges	I.8-1
8.3.1 Traffic hazards	I.8-2
8.3.2 Hazards from suspended equipment	I.8-2
8.4 Safety precautions while wading	I.8-2
8.4.1 General	I.8-2
8.4.2 Assessing the situation	I.8-2
8.4.3 Wearing of life jackets	I.8-2
8.4.4 Safety lines and taglines	I.8-2
8.4.5 Wading technique	I.8-2
8.4.6 In case of mishap	I.8-2
8.5 Safety precautions while working from boats	I.8-3
8.5.1 General	I.8-3
8.5.2 Life jackets and safety equipment	I.8-3
8.5.3 Use of taglines	I.8-3
8.5.4 Use of dinghies	I.8-3
8.6 Safety precautions when working with cableways	I.8-4
8.7 Safety precautions when handling equipment	I.8-4
8.7.1 Surveying	I.8-4
8.7.2 Chainsaws	I.8-4
8.7.3 Electrical equipment	I.8-4
8.7.4 Power tools	I.8-4
8.7.5 Protective clothing and safety equipment	I.8-4
8.7.6 Radioactive equipment	I.8-4
8.7.7 Safety aspects of groundwater monitoring	I.8-5
8.7.8 Dust menace	I.8-5
8.8 Safety precautions when handling chemicals	I.8-5
8.9 Special precautions for cold conditions	I.8-6

	<i>Page</i>
8.9.1 Hypothermia (exposure)	I.8-6
8.9.2 Frostbite	I.8-6
8.9.3 Working on ice-cold lakes and streams	I.8-6
8.9.4 Working in mountainous areas	I.8-7
8.9.5 Cold-water survival	I.8-7
8.10 Special precautions for hot conditions	I.8-7
8.10.1 Heatstroke (hyperthermia)	I.8-7
8.10.2 Sunburn	I.8-8
8.11 Travel and transport	I.8-8
8.11.1 General	I.8-8
8.11.2 Helicopters	I.8-8
8.11.3 Motor vehicles	I.8-8
8.12 Survival kits and rations	I.8-9
8.13 Other hazards	I.8-10
References and further reading	I.8-10
CHAPTER 9. DATA PROCESSING AND QUALITY CONTROL	I.9-1
9.1 General	I.9-1
9.2 Principles, conventions and standards	I.9-1
9.2.1 Conservatism, evidence and guesswork	I.9-1
9.2.2 Data accuracy standards and requirements	I.9-1
9.3 Coding	I.9-3
9.3.1 General	I.9-3
9.3.2 Developing codes	I.9-3
9.3.3 Location codes	I.9-3
9.3.4 Variable (parameter) codes	I.9-4
9.3.5 Data qualification codes	I.9-4
9.3.6 Missing data codes	I.9-4
9.3.7 Transmission codes	I.9-4
9.3.8 Geographical Information Systems	I.9-4
9.4 Data capture	I.9-5
9.4.1 Key entry	I.9-5
9.4.2 Capturing chart data	I.9-5
9.4.3 Punched-tape data	I.9-6
9.4.4 Electronic data logging	I.9-6
9.5 Primary processing activities	I.9-6
9.5.1 General	I.9-6
9.5.2 Preliminary checking of data	I.9-6
9.5.3 Traceability and processing	I.9-8
9.5.4 Data registers and tracking	I.9-8
9.5.5 Identification and retention of original records	I.9-9
9.5.6 Data adjustments for known errors	I.9-9
9.5.7 Aggregation and interpolation of data	I.9-10
9.5.8 Computation of derived variables	I.9-10
9.5.9 Data status	I.9-10
9.6 Specific primary processing procedures	I.9-10
9.6.1 Climatological data	I.9-11
9.6.2 Streamflow data	I.9-12
9.6.3 Water-quality data	I.9-14
9.7 Secondary processing	I.9-15
9.7.1 Routine post-computation tasks	I.9-15
9.7.2 Inserting estimates of missing data	I.9-15

	<i>Page</i>
9.8 Validation and quality control	I.9-17
9.8.1 General procedures	I.9-17
9.8.2 Techniques for automated validation	I.9-17
9.8.3 Routine checks	I.9-18
9.8.4 Inspection of stations	I.9-18
9.8.5 Checking manually collected data	I.9-19
9.8.6 Checking chart data	I.9-20
9.8.7 Checking logged data	I.9-20
9.9 Specific validation procedures	I.9-20
9.9.1 Flow data	I.9-20
9.9.2 Stage (water level)	I.9-20
9.9.3 Rainfall	I.9-21
9.9.4 Climatological data	I.9-23
9.9.5 Snow and ice data	I.9-24
9.9.6 River-gauging data	I.9-24
9.9.7 Water-quality data	I.9-26
9.9.8 Sediment data	I.9-26
9.10 Recording uncertainty	I.9-26
References and further reading	I.9-26
CHAPTER 10. DATA STORAGE, ACCESS AND DISSEMINATION	I.10-1
10.1 Introduction	I.10-1
10.1.1 The importance of data	I.10-1
10.1.2 Data management processes	I.10-1
10.2 Data storage and retrieval	I.10-4
10.2.1 Storage of data	I.10-4
10.2.2 Storage methods	I.10-4
10.2.3 Types of data and information to be stored	I.10-7
10.3 Data retrieval	I.10-15
10.3.1 Data analysis tools	I.10-15
10.3.2 Extraction of single variable data	I.10-16
10.3.3 Data retrieval system	I.10-16
10.4 Data dissemination	I.10-18
10.4.1 General	I.10-18
10.4.2 Catalogues of data availability	I.10-19
10.4.3 Summary reports	I.10-22
10.4.4 Yearbooks	I.10-22
10.4.5 Data export on request	I.10-23
10.4.6 Data-exchange formats	I.10-26
References and further reading	I.10-28
ANNEX. Abbreviations and acronyms	I.A-1

PREFACE

In September 2000, world leaders agreed to the United Nations Millennium Declaration, from which was soon derived a set of eight time-bound and measurable goals and targets for combating poverty, hunger, disease, illiteracy, environmental degradation and gender inequality. These eight objectives are known as the United Nations Millennium Development Goals (MDGs). The attainment of each of these Goals depends, to a great extent, on the availability of appropriate freshwater and on the protection of the population from the ravages of flooding. This, in turn, places a major responsibility on the National Hydrological and Hydrometeorological Services to support the necessary actions at the national level, in the face of ever-increasing demands on the limited freshwater resources available to WMO Members. In trans-boundary basins, in particular, where concerns are often driven by the need for equitable distribution of these limited resources, appropriate operational mechanisms to share them may have to be established and maintained among the relevant riparian countries.

One of the purposes of the World Meteorological Organization (WMO) is to promote the standardization of meteorological and hydrological observations and to ensure uniform publication of observations and statistics. With this objective, the World Meteorological Congress has traditionally adopted Technical Regulations laying down the meteorological and hydrological practices and procedures to be followed by Members of the Organization. These *Technical Regulations* (WMO-No. 49) are supplemented by a number of manuals and guides describing in more detail the practices and procedures that Members are requested or invited to follow, respectively, in monitoring and assessing their respective water resources. It is therefore hoped that improved uniformity and standardization in hydrological practices and procedures will also contribute to enhanced collaboration among WMO Members and further facilitate regional and international cooperation.

The aim of the *Guide to Hydrological Practices* is to provide the relevant information on current practices, procedures and instrumentation to all those engaged in the field of hydrology, thereby enabling

them to carry out their work more successfully. Complete descriptions of the theoretical bases and the range of applications of hydrological methods and techniques are beyond the scope of this guide, although references to such documentation are provided wherever applicable. Detailed procedures for monitoring hydrological parameters are dealt with in the specific WMO Manuals.

It is hoped that this guide will be of use, not only to Members' National Services, but also to various other stakeholders and agencies involved in water resources management in general, and in water resources monitoring and assessment in particular. The WMO Commission for Hydrology (CHy) has therefore decided to make this guide a "living" document, which will be updated periodically and posted on the Internet. This Guide will also represent one of the building blocks of the WMO Quality Management Framework – Hydrology, which is currently being developed in order to support Members and their National Services by ensuring that the activities they undertake, such as hydrological data acquisition or delivery of services and products, are indeed performed efficiently and effectively. Users of the Guide are therefore invited to continue providing their comments and suggestions for its further improvement.

The *Guide to Hydrological Practices* is published in English, French, Russian and Spanish. However, as with previous versions, several Members have announced their intention to translate this Guide into their national languages.

It is a pleasure to express my gratitude to the WMO Commission for Hydrology for taking the initiative to oversee the revision of the *Guide to Hydrological Practices*.

(M. Jarraud)
Secretary-General

ACKNOWLEDGEMENTS

Following the expressed needs of its members, the Commission for Hydrology decided to update and publish this, the sixth edition of the *Guide to Hydrological Practices* (Guide). This decision was made based on comments and experiences in using the fifth edition of the Guide and recognizing its great value to the National Hydrological Services and professionals working in water-related fields. More than 40 seasoned experts from around the world have contributed to the preparation of this edition. As a result, it is oriented towards practical applications and to fit within a quality management framework that is being initiated by the Commission for Hydrology. It is with great pleasure that I express the gratitude of the Commission to those experts who volunteered to be involved in the material compilation and preparation process, and enabled this enormous task to be accomplished.

I extend my deep appreciation to the members of the Review Committee established by the Commission for Hydrology that has overseen the revision of the Guide. The Review Committee headed by Karl Hofius (Germany), and consisting of Suresh Chandra (India), Denis Hughes (South Africa), Fred Kyosingira (Uganda), Paul Pilon (Canada), Marco Polo Rivero (Venezuela) and Avinash Tyagi (Director, Climate and Water Resources Department, World Meteorological Organization (WMO), was instrumental in identifying the areas in the fifth edition that required revision and updating, identifying the experts responsible for redrafting and peer review of various chapters and sections, and carrying out the review of the experts' contributions.

I express my sincere thanks and recognition to the experts who contributed to the redrafting and revision of the Guide. The following experts contributed to the updating and revision of the chapters (indicated in brackets) of Volume I of the Guide: Svein Harsten (Chapters 2 and 5); Robert Halliday (Chapter 2); Chris Collier (Chapter 3); Karan S. Bhatia (Chapter 4); Ahmed Fahmi (Chapter 5); Anthony Navoy (Chapter 6); Anne Coudrain (Chapter 7); Albert Rugumayo (Chapter 8); John Fenwick (Chapter 9); and Matthew Fry and Frank Farquharson (Chapter 10).

Peer review of the material prepared for the chapters was provided by the following experts: Robert Halliday (Chapter 2); Nicholas Kouwen (Chapter 3); Mauro Greppi (Chapter 4); Svein Harsten (Chapter 5); Giovanni Maria Zuppi (Chapter 6); Valerio Vendegna (Chapter 7); Filippo Thierry and Fabio

Santamaria (Chapter 8); Maria-Monica Ghioca (Chapter 9); and Bruce Stewart (Chapter 10).

The following experts contributed to the revision of the chapters and sections (indicated in brackets) of Volume II of the Guide: Arni Snorrasson (Chapter 2); Paul Mosley (material taken from Chapter 2); Bruce Mitchell (Chapter 3); Tinus Basson (4.2); Suresh Chandra (4.3); P.B.S. Sarma (4.4); Valdemar Andrade (4.5); Denis Mosnier (4.5); Benno Droege (4.6); Carlos Tucci (4.7); Shankar B. Kulkarni (4.8); Carlos Meier (4.9); Kaz Adamowski (Chapter 5); Zbigniew W. Kundzewicz (Chapter 6); and Curt Barrett, Kosta Georgakakos, Ian Cluckie, Paul Pilon, Sergei Borsch and James Dent (Chapter 7). Contributions on the latest technological developments in remote-sensing were provided by Edwin Engman and Ahalam Shalaby in various chapters.

Peer review of the material prepared for Volume II was carried out by the following experts: Paul Pilon (Chapter 3); Richard Muller (4.2); Ponnuswami Sooriyakumaran (4.3); Mario Fugazza (4.4); Valdemar Andrade and Denis Mosnier (4.5); Hussam Fahmy and Maha Tawfik (4.6); Jim Elliott (4.7); Christophe Ancey (4.8); Denis Hughes (4.9); Manuel Irigoyen and Ezio Todini (Chapter 5); Paolo Mignosa (Chapter 6); Ilmar Karro and Liljas Eric (Chapter 7). Giacomo Teruggi, John Bassier and Arthur Askew provided strong and essential support to the publication process through active coordination with the authors and performing the necessary technical editing. Above all, the publication would not have been possible without the active support of the WMO Secretariat staff.

The sixth edition of the Guide will be a living document and its Web version will be updated as and when there are significant developments in the practices in any particular field. As it is applied and used in practice, the Guide may be improved through comments and suggestions from the hydrological community. The Commission for Hydrology will endeavour to keep the Guide as up to date as possible by considering the feedback from its members.

(Bruce Stewart)
President, Commission for Hydrology

CHAPTER 1

INTRODUCTION

1.1

BACKGROUND

Hydrology is the science that deals with the occurrence and distribution of the waters of the Earth in time and space, both above and below the land surface, including their chemical, biological and physical properties, and their interaction with the physical environment (WMO/UNESCO, 1992). It provides an understanding of various phases of water as it passes from the atmosphere to the Earth and returns to the atmosphere. As such, it forms the basis for water resources assessment and management and the solution of practical problems relating to floods and droughts, erosion and sediment transport and water pollution. Increasing stress on the available water resources in the search for improved economic well-being and concerns for the pollution of surface water and groundwater have highlighted the central role of hydrology in all water and environment initiatives.

To provide guidance in monitoring this vital resource, which is central to the development and well-being of humankind, the World Meteorological Organization (WMO) Commission for Hydrology, at its first session (Washington DC, 1961), recognized the urgent need for the preparation of a guide to the relevant operational practices. As a result, the first edition was published in 1965 as the *Guide to Hydrometeorological Practices*.

The second and third editions of the Guide were published in 1970 and 1974, respectively. The third edition was entitled *Guide to Hydrological Practices* in recognition of the broader scope of its contents. Subsequently, during its fifth session (Ottawa, 1976), the Commission approved the revision of and substantial additions to the Guide to produce a fourth edition, which was issued in two volumes. Volume I dealt with data acquisition and processing and Volume II with analysis, forecasting and other applications. Volumes I and II of the fourth edition were published in 1981 and 1983, respectively. With the evolution of technology, and the evolution of the Hydrology and Water Resources activities within WMO, the fifth edition of the Guide was published in 1994 as one consolidated volume. It was also published on a CD-ROM for easy outreach to a wider water management community, beyond the traditional WMO constituency.

In 1999, the World Meteorological Congress adopted "Weather, Climate and Water" as the official subtitle of the Organization and the Commission for Hydrology, at its eleventh session in Abuja, Nigeria, in 2000, recommended that the sixth edition of the Guide be published as a live document to be uploaded to the Internet and updated more frequently, as and when required.

1.2

SCOPE

The accepted principles of integrated water resources management dictate that, in order to achieve environmental sustainability and economic productivity, rivers must be managed at the basin level. Today, when water is perceived to be everybody's business, various stakeholders, at the national as well as at international level, participate and play important roles in the process. Many institutions and agencies within a country are engaged in the collection of hydrological data and information. These data may be collected by various agencies using different measurement procedures. The resulting lack of homogeneity in the observations gives rise to a lack of confidence. It is imperative, therefore, that all these partners be made aware of the manner in which the hydrological data are collected, the limitations and the reliability of the data, and how they are to be managed by the responsible organizations in the basin. Transparency in data collection, storage and sharing is an essential element for cooperation among various users. A quality management framework for hydrometry and hydrological information is fundamental in using hydrological information from diverse sources.

The growing demand for freshwater resources has increasingly focused the attention of governments and civil society on the importance of cooperative management. Sharing the benefits of cooperation and even conflict prevention stem from a broad understanding of the principles and mechanisms through which these results can be achieved. Transboundary rivers have the potential to bring countries together both economically and politically or, conversely, they can cause economic and political tensions. The risk factor in decision-making in water resources management is a

function of hydrological variability. The risks can be mitigated through cooperative management of transboundary rivers. Cooperation in transboundary river management is fundamentally a political activity. Allocation of the resources or distribution of the benefits is essentially dependent on the knowledge of water availability and the related hydrological variability. A shared and accepted knowledge of the resources, their projected availability and the confidence in their accuracy greatly help in assessing the feasibility and fairness of alternative management and investment scenarios.

A lack of homogeneity in the data on the land phase of the hydrological cycle limits the scientific capacity to monitor changes relevant to climate and to determine the causes of variability and change in the hydrological regime. River discharge has a role in driving the climate system, as the freshwater flows into the oceans may influence thermohaline circulation. For easy and reliable use, the quality of such data, and the procedures for its acquisition, storage and exchange should in general follow certain specified standards and protocols.

All of these factors increased the need for ensuring the quality of hydrological data. WMO, with a vision to provide expertise in international cooperation in weather, climate, hydrology and water resources, issues international guidance material and standards, and it is hoped that this Guide will form an important link in the quality management framework for hydrological practices. To meet such requirements, continuing efforts have been made to expand and improve the Guide, now in its sixth edition. It is expected that this Guide will be useful to agencies – not only to National Hydrological Services, but also to other stakeholders.

This Guide addresses all aspects of the land phase of the hydrological cycle, especially its phases upon and under the surface of the land. In conjunction with the manuals published by WMO, it provides detailed information on those areas that fall within the scope of the hydrology and water resources activities of the Organization designed to support National Hydrological Services and services with a similar mission.

The Guide forms part of an overall framework of recommended practices and procedures provided by *Technical Regulations* (WMO-No. 49) Volume III – Hydrology, as approved by WMO. Members are invited to implement these recommended practices and procedures in developing their Hydrological Services and activities.

1.3

CONTENTS OF THE GUIDE

It is difficult to set a clear dividing line between the science of hydrology and the practice of water resources planning and management. Nevertheless, for very practical reasons, it was necessary to divide this edition of the Guide into two volumes as explained below (Figure I.1).

Volume I, entitled *Hydrology – From Measurement to Hydrological Information*, deals with networks, instruments, methods of observation and primary data processing and storage. It contains ten chapters, beginning with an introduction and an outline of the contents in Chapter 1.

Chapter 2, entitled *Methods of observation*, deals with the design and evaluation of hydrological networks and provides an overview of instruments and methods of observation for various hydrological elements that are described in detail in the subsequent chapters. Precipitation measurement in Chapter 3 is covered in all its aspects ranging from the location of raingauges to the observation of precipitation by remote-sensing. The chapter covers both liquid and solid precipitation, including their quality. Chapter 4, *Evaporation, evapotranspiration and soil moisture*, addresses both direct and indirect methods and also briefly reviews methods for evaporation reduction.

Chapter 5, *Surface Water Quantity and Sediment measurement*, is pivotal and deals with measurement of flow in rivers and the capacity of lakes and reservoirs. It is also concerned with the measurement of sediment discharge. This subject matter is discussed in greater detail in the *Manual on Stream Gauging* (WMO-No. 519) and the *Manual on Operational Methods for the Measurement of Sediment Transport* (WMO-No. 686), to which the reader is invited to refer for more information.

Chapter 6, which is entitled *Groundwater*, is concerned with measurements from wells and the hydraulic properties of aquifers. It also looks in some detail at various remote-sensing techniques for groundwater observation.

The development of water resources is not only constrained by their availability in quantity but also by their quality. Accordingly, Chapter 7, *Water quality and aquatic ecosystems*, addresses subjects ranging from sampling methods to remote-sensing. Chapter 8, *Safety considerations in hydrometry*, discusses all the topics ranging from the safety of the personnel performing the measurements to

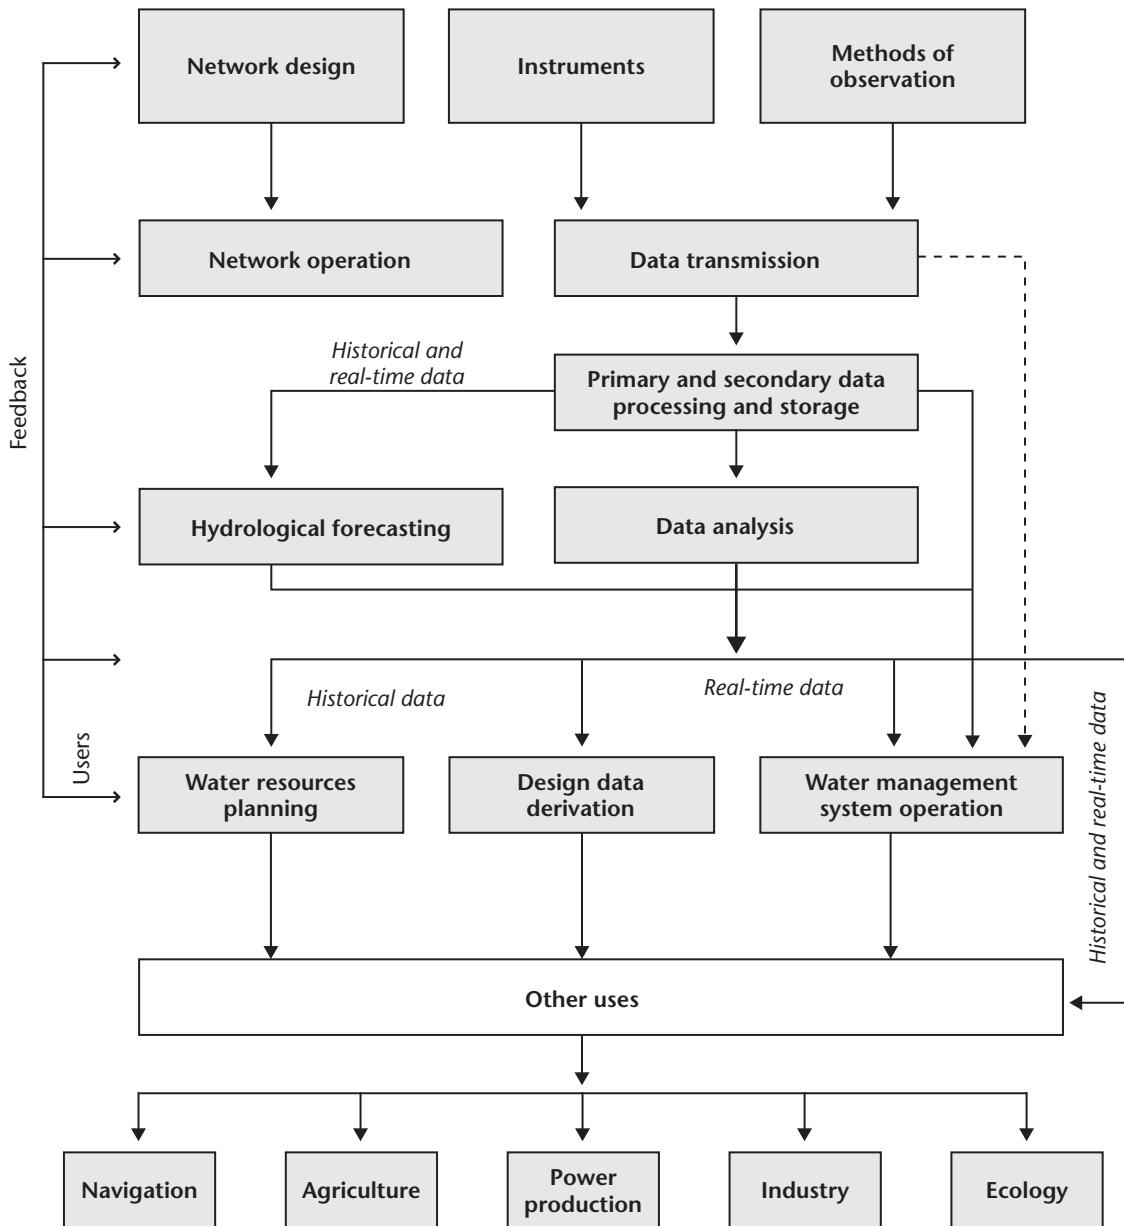

Figure I.1.1. System of hydrology

safeguarding recording stations and the samples collected.

Lastly, Chapters 9 and 10, Data processing and quality control and Data storage, access and dissemination, respectively, include the dissemination of data for use by the wider water community.

Volume II deals with the application of the information referred to above in hydrological forecasting and the planning and design of various water projects. Accordingly, the volume is entitled Management of Water Resources and Application of Hydrological Practices. It consists of seven

chapters beginning with an introduction and outline of the contents in Chapter 1.

Chapter 2 provides guidance on the management of hydrological services, including human resources aspects and financial and asset management. Chapter 3 introduces integrated water resources management and emphasizes the vital role of quality hydrological data in addressing various complex water management issues. Chapter 4 highlights the use of hydrological information in applications to water management, namely estimating reservoir capacity and yield, flood management, irrigation and drainage, hydropower and energy-related

projects, navigation and river training, urban water resources management, sediment transport and river channel morphology and environmental issues. Chapter 5 deals with extreme value analysis, and Chapters 6 and 7 address the modelling of hydrological systems and hydrological forecasting, respectively, as two of the key functions of Hydrological Services in water management.

While a measure of standardization is desirable and can be achieved with respect to instruments, methods of observation and publication practices, this is rarely the case with respect to hydrological analysis and applications. Therefore, the emphasis in Volume II is on presenting alternative approaches to the solution of selected problems, which have been demonstrated, through experience, to be both practical and effective. Rather than recommending any approach or technique in preference to another, attention is drawn to the principal features and advantages of each approach. The final choice of approach will depend on a multitude of factors, including the relevant hydrological and climatic regimes, available data and information and the purposes to be served, and can only be made in the light of a full understanding of the individual situation. During the past few years, the increasing availability of microcomputers has permitted the introduction of more sophisticated analytical methods and techniques. Some of these have now been widely adopted in practice and they have therefore been introduced into this Guide.

The space limitations of this Guide restrict the amount of material that can be presented. For more detailed information on the subjects treated, the reader should consult the following publications: for discharge measurement, the *Manual on Stream Gauging* (WMO-No. 519, Volumes I and II) and, on sampling, the *GEMS/Water Operational Guide* (UNEP, 2005). The reader is also referred to international standards dealing with methods for liquid flow measurements in open channels prepared by member countries of the International Organization for Standardization (ISO). ISO has developed more than 50 standards for various types and methods of measurement. Valuable references can also be found in the proceedings of the international symposiums, seminars and workshops on hydrometry organized by the International Association of Hydrological Sciences (IAHS), WMO and the United Nations Educational, Scientific and Cultural Organization (UNESCO).

A full description of the theoretical base for the recommended practices, and detailed discussion of

their methods of application are beyond the scope of this Guide. For such details, the reader is referred to appropriate WMO manuals and technical reports, as well as to other textbooks, handbooks and technical manuals of national agencies. In particular, further detailed guidance on instruments and methods of observation is given in the *Guide to Meteorological Instruments and Methods of Observation* (WMO-No. 8) and the *Guide to Climatological Practices* (WMO-No. 100).

References appear at the end of each chapter.

1.4 THE HYDROLOGICAL OPERATIONAL MULTIPURPOSE SYSTEM

In recent decades, hydrological science and technology have made substantial progress and significant contributions have been made by field hydrologists to the development and management of water resources. So as to facilitate the sharing of hydrological practices among the National Hydrological Services, a technology transfer system known as the Hydrological Operational Multipurpose System (HOMS) was developed by WMO and has been in operation since 1981. It offers a simple but effective means of disseminating information on a wide range of proven techniques for the use of hydrologists. HOMS transfers hydrological technology in the form of separate components. These components can take any form, such as a set of drawings for the construction of hydrological equipment, reports describing a wide variety of hydrological procedures and computer programs covering the processing and storage of hydrological data, as well as modelling and analysis of the processed data. To date, over 180 components have been made available, each operationally used by their originators, thus ensuring that every component serves its purpose and has been proved in practice. These descriptions appear in the *HOMS Reference Manual* (HRM) which is available online at http://www.wmo.int/pages/prog/hwsp/homs/homs_en.html in the English, French, Russian and Spanish languages. The present Guide is further enriched through cross-references to the relevant HOMS components, which are included at the beginning of the relevant sections of this Guide.

CHAPTER 2

METHODS OF OBSERVATION

2.1

INTRODUCTION – THE HYDROLOGICAL CYCLE AS THE SUBJECT OF OBSERVATION

Water is found on Earth in significant amounts in all three of its physical phases: liquid, solid and gaseous. It is also found in all three of Earth's major environments that are readily accessible to humans: the atmosphere, the seas and oceans, and the land masses. As water can readily move from one environment to another and can change from one phase to another in response to its environment, it is a dynamic medium in both space and time. The Earth's system of repositories for the storage of water and the multitude of paths among the many repositories has been conceptualized as a cycle, as shown in Figure I.2.1. The science of hydrology has not traditionally encompassed the entire hydrological cycle, but has been limited to the land portion of the cycle and its interactions with the oceans and atmosphere.

Because humankind spends a predominant amount of time on the land surface and water is both a necessity for life and a potential hazard to it, hydrological knowledge is valuable in providing for our continuity and well-being. One traditional means by which hydrological knowledge has been accumulated is through measurement of the storage and flow of water at distinct points in time and space. Such measurements, also known as data, are analysed and synthesized to generate hydrological knowledge or information. Volume II of this Guide deals with hydrological analysis.

Two of the basic equations that describe the physics of the hydrological cycle are also pertinent in describing the systems that are used to make measurements of its transient properties: (a) the equation of continuity of mass; and (b) the equation of continuity of energy. For example, one form of the equation of continuity of mass:

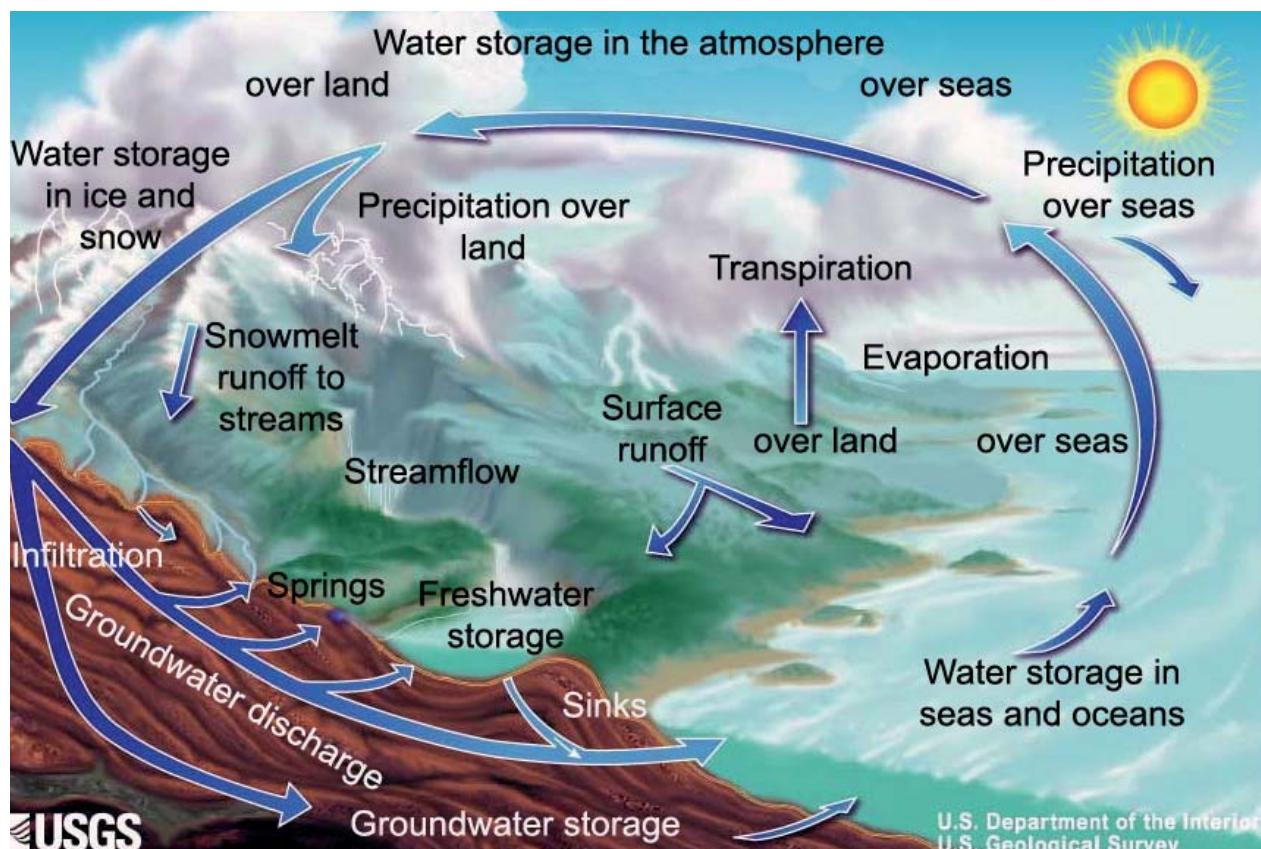

Figure I.2.1. The hydrological cycle

$$Q = AV \quad (2.1)$$

often serves as the basis for the determination of the flow rate in a stream or canal. In this equation, Q is the instantaneous rate of flow through a cross-section of channel with area, A and average flow velocity, V . Traditionally, flow rate, also known as discharge, could not be measured directly for streams of even a modest size. A cross-sectional area, however, can be measured by sampling its spatial dimensions, and velocities can be sensed by the use of current meters. Thus, the use of this equation, described in detail in Chapter 5, has permitted determinations of the rate of discharge of even the largest rivers of the world.

Another example of the role of the equation of continuity of mass can be found in the observation of evaporation of water from a lake surface. In this example, the equation takes the form:

$$P + I - O - E = \Delta S \quad (2.2)$$

where P is the amount of precipitation that falls onto the surface of the lake during a period of observation, I is the inflow of surface water and groundwater during the period, O is the outflow of surface water and groundwater, E is the quantity of water evaporated from the surface of the lake during the period, and ΔS is the change in the volume of water in the lake during the period.

Precipitation can be measured according to the techniques described in Chapter 3; inflows and outflows can be measured using techniques described in Chapters 4, 5 and 6; changes in the lake contents can be computed by relating the lake-surface elevations at the beginning and the end of the observation period to the respective contents at those times; and water-level measurement is discussed in Chapter 5. By measuring or otherwise observing four of the five terms in equation 2.2, the fifth, evaporation, can be computed algebraically.

Systematic hydrological observations are at the very core of the development of databases, information and knowledge required for the effective management of water resources. This chapter discusses a number of subjects that are fundamental to the operation of hydrological and meteorological observing networks and to the production hydrological information.

The chapter provides an overview of hydrological standards and codes, accuracy of measurements,

concepts of network planning, methods of observation, measurement of physiographic characteristics, the role of hydrological data in information systems and the linkages to sustainable development. Some of these subjects are discussed in greater detail later in this Volume. Where this is the case, cross-references are provided.

2.2 WATER RESOURCES INFORMATION SYSTEMS

2.2.1 Need for data and information

The report of the International Conference on Water and the Environment (ICWE), held in Dublin in January 1992 (United Nations, 1992a), provides a compelling assessment of the importance of water resources to the world's environment and to its economy. Its specific policy statements highlight very effectively the role that hydrological services should play in achieving goals related to sustainable development. ICWE addressed the following issues:

- (a) Integrated water resources development and management;
- (b) Water resources assessment and impacts of climate change on water resources;
- (c) Protection of water resources, water quality and aquatic ecosystems;
- (d) Water and sustainable urban development and drinking water supply and sanitation in the urban context;
- (e) Water for sustainable food production and rural development, and drinking water supply and sanitation in the rural context;
- (f) Mechanisms for implementation and coordination at the global, national, regional and local levels.

Volume II, Chapter 3, reviews the evolution of integrated water resources management and provides examples of best practices. The nature of the information that will be required to meet the needs of integrated water resources management is difficult to project. Perhaps, the best ideas can be gathered from considering recent trends in water management (2.2.4). Since data are gathered for the use of water managers, whether in government or private agencies, changes in the way water is managed will influence the data and information demands.

The impacts of these changes may include:

- (a) Growing competition for water, resulting in a higher value being placed on available supplies

- and, ultimately, goods and services being redefined in terms of their water content – this could be exacerbated by declining water availability and quality in many areas;
- (b) Economic pressures resulting in more user fees, cost sharing and local financing of water programmes, with a concurrent shift in emphasis from water development activities to environmental programmes and demand management;
 - (c) Increased focus on water conservation and reuse in all phases of project development – in some areas, reclaimed water now costs less than freshwater supply;
 - (d) Environmental legislation designed to hold polluters and users accountable for their impacts on available supplies;
 - (e) Legal measures to ensure that users and water managers justify their needs, uses and management practices, and that increased priority be accorded to environmental water uses (for example, fish and wildlife habitat) versus the traditional economic uses (for example, agriculture and industry);
 - (f) Emphasis on basin and regional water planning as a means of resolving transboundary issues and disputes.

These trends indicate that greater coordination of data-collection efforts will be required to meet the needs of water managers in the future. Water management is becoming more integrated across disciplines and specialities; therefore, compatible data on quantity and quality of surface water and groundwater, and on specific basins and regions will be required. Current problems related to data accessibility, compatibility and reliability will have to be resolved to meet these needs. In addition, water management challenges are closely linked to those of environmental management or ecosystem management. Therefore, an increasingly holistic management approach is required.

While many users will continue to need data for design and analysis purposes, increased attention must be paid to the need for comprehensive regional surface-water information that can be applied to many different kinds of water issues and problems. This means that overview information, fact sheets and summaries, surface-water and precipitation mapping, hydrological assessments of basins and regions, and water information relevant to the assessment of water quality and groundwater problems must be available. The use of real-time water data will continue to grow to serve many needs.

2.2.2 Hydrological information systems

This Volume of the Guide deals with the field activities of operational hydrology. However, the data that are generated by the field activities are of little or no value if they cannot be readily and confidently accessed by the potential data users. Operational hydrology within a given Hydrological Service can be considered as an information system providing a conceptual basis for the development of proper approaches, which ensure that the right data are available in the right form at the right place and time. Figure I.2.2 depicts the elements of a hydrological information system. Ideally, the information system is embedded in a natural sequence of actions and decisions that begins with the perception of an opportunity and culminates in the implementation of decisions that maximize the net positive impacts of the opportunity.

A hydrological information system combined with a suite of numerical models – physical, statistical or socio-economic – comprises a decision support system. With the decision support requirements firmly in mind, the designer of the information system can specify the procedures to be used to analyse the hydrological data. These data-analysis technologies may be any one model or a combination of models that account for the probabilistic, stochastic or deterministic natures of the hydrological phenomena of interest. Volume II of this Guide (in particular Chapters 5 to 7) discusses many of these data-analysis technologies.

The actual data collection can begin at this point in the sequence, and it is also at this point that feedback, represented as dashed arrows in Figure I.2.2, begins to take place. All of the previous steps have been based on a specific level of knowledge about the hydrological conditions of interest. As data are collected, this level increases, and new data-analysis techniques and new network designs may become appropriate. Guidance on data collection is given in 2.5.

From Figure I.2.2, it is possible to see that quality assurance is an integral phase of the information system that is relevant throughout the continuum from field activities to the dissemination of data and information. Owing to its pervasive nature, quality-assurance guidance can be found throughout this Volume.

No discussion of information systems is complete without mention of data management systems. The information contained in a robust data-management system is available, not only for the uses for which

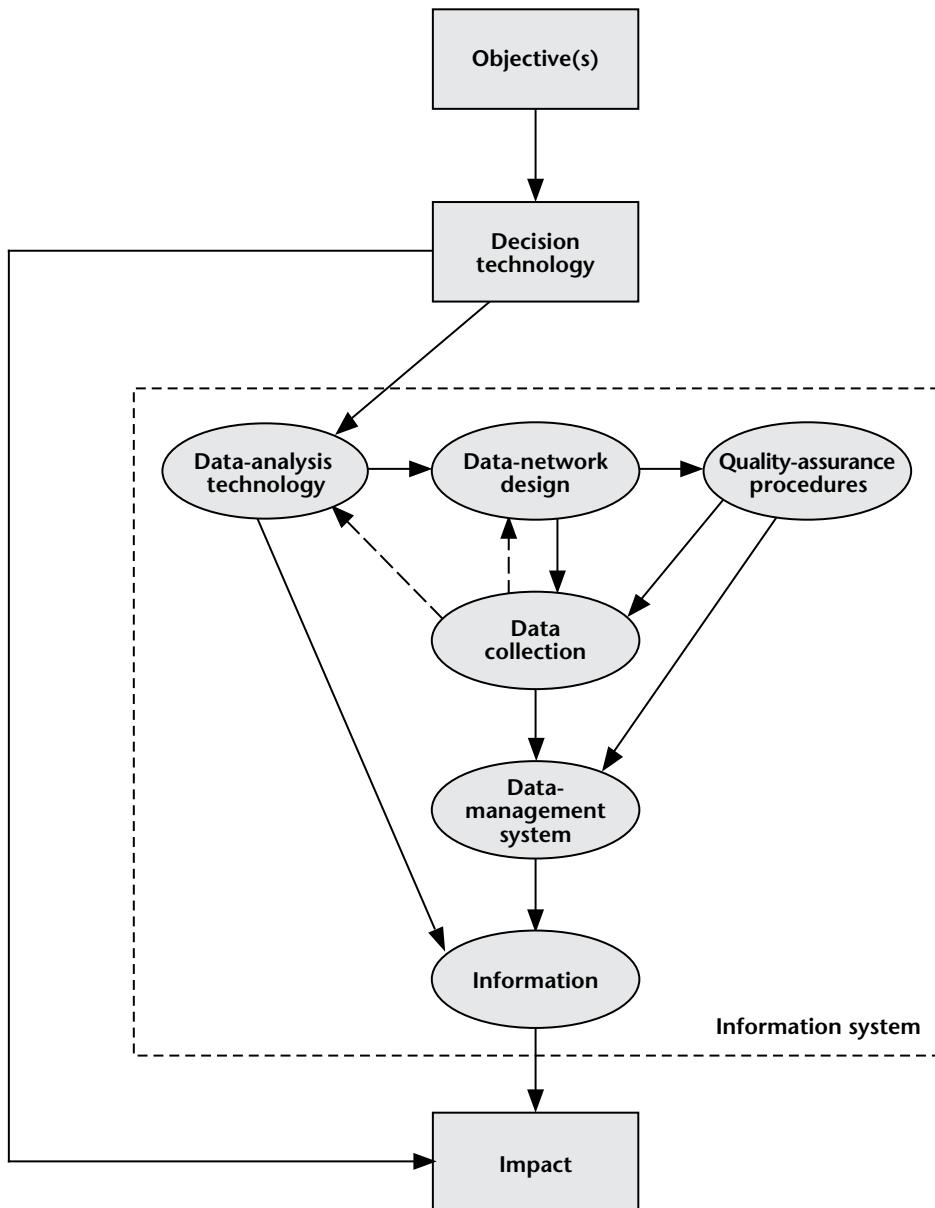

Figure I.2.2. Components of a hydrological information system

the data were collected originally, but also for a multitude of uses that may never have been anticipated. However, with robustness comes a price. The options inherent in robust systems tend to make them difficult to use, as more training is required. This represents the first portion of the price. This part of the cost can be minimized by user-friendly systems designs. The second cost factor is the potential loss of information that robustness entails. As a data-management system cannot be all things to all people, compromises must be made, which usually result in data compaction and loss of data attributes. To reduce such loss, subsystems that retain more objective-specific data can be appended to the robust, central

system. Such systems are discussed in Chapter 10. Current technology also allows the development of distributed hydrological information systems having searchable metadata. Provided that computer security matters are fully considered, such virtual data systems provide an effective and robust means of accessing data and information required for decision-making.

The ultimate product of the information system is obtained by processing the data through the same data-analysis technology that was initially crucial in the design of the data network. The sequence culminates by integrating the hydrological information into the decision process for which it was

designed to have an optimal impact. The key to obtaining this optimality is the compatibility among the decision technology, the data-analysis technology and the data network.

A well-designed information network contains synergism that is derived in three ways. First, information is a commodity that is not destroyed by its use. Thus, if properly preserved, it can be made available at minimal cost for many uses not anticipated at the time of its collection. Secondly, information can be used to improve understanding of hydrological processes. By improving process understanding, both the information content of the existing data and all future data are increased. Thirdly, synergism evolves by taking advantage of the accomplishments of others. New approaches and technologies for the design of information systems, like the data they contain, are recyclable commodities.

2.2.3 Uses of water resources information

Hydrological or Hydrometeorological Services or related agencies have been established in countries for systematic water resources data collection, archiving and dissemination described elsewhere in this Volume. Their primary role is to provide information to decision makers on the status of and trends in water resources. Such information may be required for the following purposes (WMO/UNESCO, 1991):

- (a) Assessing a country's water resources (quantity, quality, distribution in time and space), the potential for water-related development and the ability of the supply to meet actual or foreseeable demand;
- (b) Planning, designing and operating water projects;
- (c) Assessing the environmental, economic and social impacts of existing and proposed water resources management practices and planning sound management strategies;
- (d) Providing security for people and property against water-related hazards, particularly floods and droughts;
- (e) Allocating water among competing uses, both within the country and cross-border;
- (f) Meeting regulatory requirements.

Most frequently, water resources information has been collected for a specific purpose, such as the design of a hydroelectricity scheme. However, increasing competition among users for scarce water requires that resources be managed in an integrated fashion, so that the interactions among several projects and users may be understood. This places a much greater burden on the suppliers of

water resources information, because a variety of types of information is simultaneously needed, and has to be presented in different forms for different users. This makes it essential that assessment agencies understand the needs of all their users, and not just those with whom they have traditionally dealt. Even more demanding is the need to look ahead to the possible needs of future users of data and to commence collecting the information before an actual demand can be demonstrated with certainty. Therefore, it is necessary that the design and updating of data-collection networks, especially the principal stations, be coordinated to ensure that stations for monitoring the various elements of the water cycle are sufficiently related, both in number and location, to achieve an integrated network (2.4). Such an approach would enhance the information content of the data sets for both current and unforeseen future needs.

With the growing recognition of such issues as global climate change and the environmental impacts of human activities, such as urbanization, there is an increasing emphasis upon the information required as a foundation for sustainable development and management of water resources. Volume II, Chapter 3, describes the rationale for integrated water resources management and presents elements of best practice.

2.2.4 Types of water resources information

The diversity of possible uses of water resources information implies that there is a considerable range of types of data. Conventional water resources information comprises the statistics of a variety of meteorological and hydrological elements. The elements include the following (WMO/UNESCO, 1991):

- (a) Precipitation, for example, rainfall, snow and fog drip;
- (b) River levels and flows, and lake and reservoir levels;
- (c) Groundwater levels;
- (d) Evapotranspiration;
- (e) Sediment concentrations and loads in rivers;
- (f) Water quality (bacteriological, chemical; and physical) of surface water and groundwater.

The statistics include the following:

- (a) Mean annual, monthly, or seasonal values;
- (b) Maxima, minima and selected percentiles;
- (c) Measures of variability, such as the standard deviation;
- (d) Continuous records in the form, for example, of a river flow hydrograph.

There is a requirement for both historical and real-time data to cater to the full range of needs from water resources planning to project design and flood warning. Flood or low flow forecasting (Volume II, Chapter 7) may require data to be synthesized for the future by using numerical flow-routing models (Volume II, 6.3.4).

The *Water-resource Assessment Activities: Handbook for National Evaluation* (UNESCO/WMO, 1988) recognizes a number of types of water resources projects for which hydrological information is required, as given in Table I.2.1.

Together, these imply a vast range of water-related data and information that the Hydrological Services and other related agencies may be required to collect and archive. Different countries have different priorities that depend on their level of economic and social development, the

sensitivity of their natural environments to disturbance by human activity, and the nature of the physical environment itself, for example, climate, topography and the abundance or otherwise of water.

There are several critical requirements for an effective water resources assessment programme:

- (a) Data of high quality must be collected to permit confident statistical analysis;
- (b) The data and the information that they provide must be carefully targeted to the requirements of users;
- (c) An integrated observation programme, in which measurements of several variables are made simultaneously, is required to provide the greatest total value;
- (d) Other forms of information that are compatible with and can be analysed with water resources information should be available;

Table I.2.1. Hydrological information required for water resources projects

Water projects	Water levels			River flow			Sediment			Water quality ^a		
	time series	max	min	time series	max	min	time series	max	min	time series	max	min
Redistribution of water (diversions, intakes, canals)	M	M	M	H	H	H	H	M	M	H	M	M
Redistribution of water in time (reservoirs)	M	M	M	H	H	H	H	M	M	H	M	M
Energy production (hydropower, waste heat disposal)	H	M	M	H	M	H	H	M	M	M	M	M
Water confiners (dams, flood banks)	H	H	M	M	H	M	M	M	M	M	M	M
Water relievers (spill ways)	M	H	M	H	H		M			M		
Quality improvements (water and sewage treatment)				H	M	H	M	M	M	H	H	H
Zoning (flood plain, scenic rivers)	H	H	M	M	H	M	M					
Insurance (flood damage, water quality damage)	H	H		H	H					H	H	
Flow and level forecasts (flood control, reservoir operation)	H	H	H	H	H	H						
Standards and legislation (water quality)	M	H	H	M	H	H				H	H	H

^a Water-quality parameters are diverse depending on the type of project.

H = High level of priority M = Medium level of priority

- (e) An effective system is needed for archiving and disseminating data to ensure that they are not lost or corrupted and that they are made available in a form that enables analysis (Chapter 10).

The above requirements can be met by the application of contemporary technologies – for example, telemetry, to make data available in near-real time – by implementing searchable computer databases, by remote-sensing to collect areal information more effectively and by Geographical Information Systems (GIS) (2.6.7) to provide a means of analysing spatial data. At the same time, new computer storage devices and the use of the Internet make the data more readily available. Nevertheless, technology is not the only requirement, and a trained and well-managed staff is of even more fundamental importance. As financial resources become increasingly limited in many countries, it becomes ever more vital that effective organizational structures are in place to ensure that those resources are used most efficiently.

In addition to the more conventional measurements, there is a growing recognition of the need to measure other aspects of the freshwater environment and of the wider environment in which freshwater is only a single component. These include:

- (a) The volumes of water needed for industrial, domestic and agricultural use, and for navigation. These are now significant modifiers of the hydrological cycle in many basins;
- (b) Attributes of rivers and required volumes of water related to instream uses, for example, freshwater fishery habitats or recreation;
- (c) Watershed characteristics that may be related to hydrology, for example, vegetation patterns, soil moisture, topography and aquifer characteristics;
- (d) Environmental concerns, for example, eutrophication of lakes and damage to natural freshwater and estuarine ecosystems.

2.3 HYDROLOGICAL SYMBOLS, CODES AND ACCURACY OF MEASUREMENTS

2.3.1 Units and symbols

Standardization of units and symbols is desirable and can be achieved through the use of those recommended in Tables I.2.2–I.2.4 (ISO, 1993). Commonly used units and conversion factors are also given. All symbols and units used in the Guide conform to those in the tables.

2.3.2 Hydrological codes

2.3.2.1 General

All systems for the transmission of data make use of some form of coding method, the purpose of which is to ensure that the information is transmitted quickly and reliably (9.3). In the case of fully automated systems, the information must be put into coded form before being processed. For these reasons, the codes are composed of standard forms that enable the information to be transmitted and given in a form compatible with processing. Such processing is usually preceded by quality control (9.8).

The structure of international codes is governed by convention, and codes are developed as a collective effort. For a long time, WMO has been developing codes to meet requirements for the exchange of meteorological data.

In operational hydrology, requirements for data are not on a worldwide scale and yet there have been a multiplicity of codes introduced in this field. This led the WMO Commission for Hydrology to develop international hydrological codes. The purpose of these codes is to cover general requirements so that, as far as possible, the procedures for coding and collecting hydrological data are standardized. The HYDRA and HYFOR codes, which were developed and used in the past, are no longer recommended for use. Instead, the character form for the representation and exchange of data (CREX) code has been developed in recent years for use in the representation and transmission of hydrometeorological data.

This code may be found to be particularly useful in the case of large national and international basins, in which a large number of stations are connected to a processing centre. The observations are coded, usually manually, by an observer, and then transmitted to a collecting centre for processing.

2.3.2.2 Character form for the representation and exchange of data

CREX is the name of a character code for the representation and exchange of meteorological, hydrological and water-quality data. Although originally designed for the exchange of data for which there were no suitable existing WMO code forms, CREX has been used recently as standard code form for data transmitted from data-collection platforms (DCPs). A CREX message shall consist of one or more subsets of related meteorological data defined, described and represented by a single CREX entity. For observational data, each subset shall correspond

1	Data description section	CREX master table number, edition number, table version number, data category, then a collection of descriptors which define the form and content of data subsets making the data section and an optional check digit indicator E
2	Data section	A set of data items defined by section 1
3	Optional section	SUPP followed by additional items for local use
4	End section	7777

Further information can be found at <http://www.wmo.int/pages/prog/www/WMOCodes.html>.

2.3.3 Accuracy of hydrological measurements

2.3.3.1 Basic principles

Theoretically, the true values of hydrological elements cannot be determined by measurements because errors of measurement cannot be eliminated completely. The uncertainty in measurement has a probabilistic character that can be defined as the interval in which the true value is expected to lie with a certain probability or confidence level. The width of the confidence interval is also called error band.

If measurements are independent one from the other, the uncertainty in the results of measurements can be estimated by taking at least

20–25 observations and calculating the resulting standard deviation, and then determining the confidence level of the results. This procedure cannot usually be followed in hydrometric measurements, because of the change in the value to be measured during the measuring period. For instance, many consecutive measurements of discharge with current meters at constant stage is clearly impracticable in field conditions. Thus an estimate of the uncertainty has to be made by examining the various sources of errors in the measurement.

Another problem in applying statistics to hydrological data arises from the assumption that observations are independent random variables from a fixed statistical distribution. This condition is seldom met in hydrological measurements. River flow is, by nature, not purely random. It depends on previous values. It is generally accepted that some aspects of the departure of hydrological data from the theoretical concept of errors is not serious. However, it should be stressed that no statistical analysis can replace correct observations, in particular because spurious and systematic errors cannot be eliminated by such analysis. Only random errors can be characterized by statistical means.

Section 2.3.3 contains definitions of basic terms related to the accuracy of hydrological measurements. Methods for estimating uncertainty are

introduced and numerical values of accuracy, required for the most important hydrological parameters, are given. References to the existing recommendations contained in the *Technical Regulations* (WMO-No. 49) and other publications are also included.

2.3.3.2 Definitions of terms related to accuracy

The definitions of the terms related to accuracy given below take into account those given in the *Technical Regulations* (WMO-No. 49), Volume III – Hydrology and in the *Guide to Meteorological Instruments and Methods of Observation* (WMO-No. 8):

Accuracy: The extent to which a measurement agrees with the true value. This assumes that all known corrections have been applied.

Confidence interval: The interval which includes the true value with a prescribed probability and is estimated as a function of the statistics of the sample (Figures I.2.3 and I.2.4).

Confidence level: The probability that the confidence interval includes the true value (Figures I.2.3 and I.2.4).

Correction: The value to be added to the result of a measurement to allow for any known systematic error and thus obtain a closer approximation to the true value.

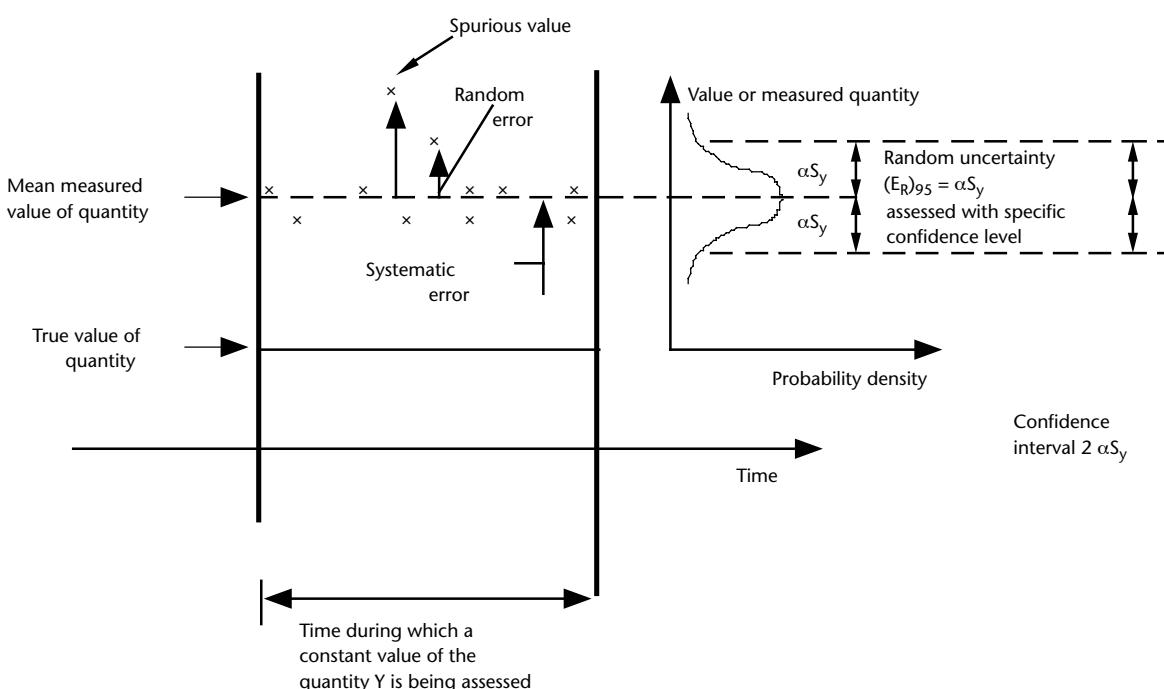

Figure I.2.3. Explanation of errors

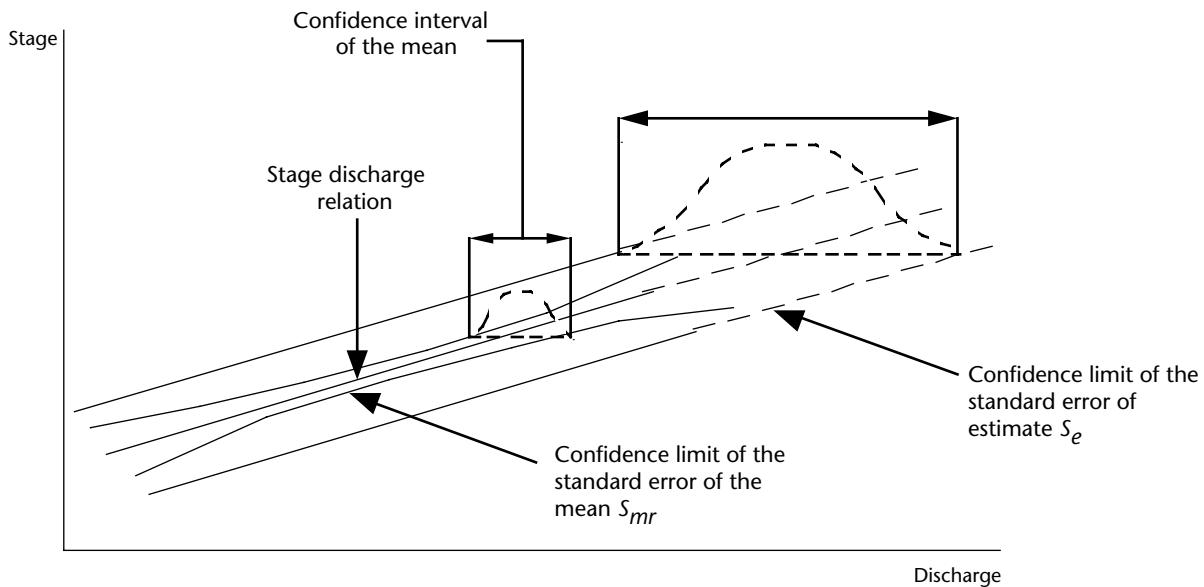

Figure I.2.4. Explanation of errors in linear regression

Error: The difference between the result of a measurement and the true value of the quantity measured. This term is also used for the difference between the result of a measurement and the best approximation of the true value, rather than the true value itself. The best approximation may be a mean of several or many measurements.

Expected value: The best approximation of the true value, which may be a mean of several, or of many measurements.

Hysteresis (instrument): That property of an instrument whereby it gives different measures, for the same actual value, according to whether that value has been reached by a continuously increasing or continuously decreasing change of the variable.

Measurement: An action intended to assign a number as the value of a physical quantity in stated units. The result of a measurement is complete if it includes an estimate (necessarily in statistical terms) of the probable magnitude of the uncertainty.

Normal distribution: A mathematically defined, symmetrical, bell-shaped, continuous distribution, traditionally assumed to represent random errors.

Precision: The closeness of agreement between independent measurements of a single quantity obtained by applying a stated measurement procedure several times under prescribed conditions. Accuracy has to do with closeness to the truth, precision has to do only with closeness together.

Precision of observation or of reading: The smallest unit of division on a scale of measurement to which a reading is possible either directly or by estimation.

Random error: That part of the error that varies in an unpredictable manner, in magnitude and in sign, when measurements of the same variable are made under the same conditions (Figure I.2.3).

Range: The interval between the minimum and maximum values of the quantity to be measured, for which the instrument has been constructed, adjusted or set. It can be expressed as a ratio of maximum and minimum measurable values.

Reference measurement: A measurement utilizing the most advanced state of science and the latest technologies. The result of the reference measurement is used to estimate a best approximation to the true value.

Repeatability: The closeness of agreement, when random errors are present, between measurements of the same value of a quantity obtained under the same conditions, that is, the same observer, the same instrument, the same location, and after intervals of time short enough for real differences to be insignificant.

Reproducibility: The closeness of agreement between measurements of the same value of a quantity obtained under different conditions, for example, different observers, instruments, locations, and

after intervals of time long enough for erroneous differences to be insignificant.

Resolution: The smallest change in a physical variable that causes a variation in the response of a measuring system.

Sensitivity: The relationship of the change of the response to the corresponding change of the stimulus, or the value of the stimulus required to produce a response exceeding, by a specified amount, the response already present due to other causes.

Spurious value: Value known for certain to be in error, for example, due to human mistakes or instrument malfunction (Figure I.2.3).

Standard deviation (s_y): This is a measure of the dispersion of values about their mean. It is defined as the positive square root of the sum of the squares of the deviation from the arithmetic mean, divided by $(n - 1)$. It is given by:

$$s_y = \left[\frac{\sum_{i=1}^n (y_i - \bar{y})^2}{n - 1} \right]^{1/2} \quad (2.3)$$

where \bar{y} is the arithmetic mean of the sample of n independent measurement of the variable y , and $(n - 1)$ indicates the loss of one degree of freedom.

Standard error of estimate (s_e): A measure of the variation or scatter of the observations about a linear regression. It is numerically similar to the standard deviation except that the linear-regression relation replaces the arithmetic mean and $(n - 1)$ is replaced by $(n - m)$:

$$s_e = \left[\frac{\sum (d)^2}{n - m} \right]^{1/2} \quad (2.4)$$

where d is the deviation of an observation from the computed regression value, m is the number of constants in the regression equation, and $(n - m)$ represent the degrees of freedom in the equation derivation.

Systematic error: That part of the error that either:

- (a) Remains constant in the course of a number of measurements of the same value of a given quantity; or
- (b) Varies according to a definite law when conditions change (Figure I.2.3).

Tolerance: The permissible accuracy in the measurement of a specified variable.

Tolerance limit: The limiting lower or upper value specified for a quantitative characteristic.

True value: The value that characterizes a quantity in the conditions that exist at the moment when that quantity is observed. It is an ideal value that could be known only if all causes of error were eliminated.

Uncertainty: The interval about the measurement within which the true value of a quantity can be expected to lie with a stated probability (Figure I.2.3). The numerical value of uncertainty is a product of the true standard deviation of the errors and a numerical parameter depending on the confidence level:

$$e = \pm \alpha s_y \approx \alpha s_y \quad (2.5)$$

The standard deviation, s_y , computed from n observations, approaches the true standard deviation, σ_y , as n approaches infinity. In the case of normal distribution of error, numerical parameters are as follows:

Confidence level	α
0.50	0.674
0.60	0.842
0.66	0.954
0.80	1.282
0.90	1.645
0.95	1.960
0.98	2.326
0.99	2.576
0.999	3.291

2.3.3.3 Types of error

Spurious errors should be eliminated by discarding the values of measurements concerned.

These errors can be identified by a statistical-outlier test, such as the one described in ISO 5168 (ISO, 2005) that gives a rejection criterion.

Systematic error originates mainly from instrumentation and cannot be reduced by increasing the number of measurements, if the instruments and conditions remain unchanged. If the systematic

error has a known value, this value should be added to or subtracted from the result of the measurement, and error due to this source should be considered zero. Systematic error should be eliminated by correcting, properly adjusting or changing the instrument, and/or by changing the flow conditions, for example, the length of straight approach channel of a stream-gauging section. These errors are often due to difficult measuring conditions, such as unsteady flow, meandering and bad location of stations.

Random errors cannot be eliminated, but their effects can be reduced by repeated measurements of the element. The uncertainty of the arithmetic mean computed from n independent measurements is several times smaller than the uncertainty of a single measurement. The distribution of random errors can usually be assumed to be normal (Gaussian). For certain cases, normal distribution can or should be replaced by other statistical distributions.

2.3.3.4 Sources of error

Each instrument and measuring method has its own sources of error. Therefore, it would be difficult to list all possible sources of error. The specific sources are usually mentioned in the descriptions of the design of the instruments and operating procedures, such as those in ISO Standards, and the *Manual on Stream Gauging* (WMO-No. 519). Some typical sources of error include:

- (a) Datum or zero error originates from the incorrect determination of the reference point of an instrument, for example, staff-gauge zero level, difference between the staff-gauge zero and the weir-crest levels;
- (b) Reading error results from the incorrect reading of the indication by the measuring instrument, for example, due to bad visibility, waves, or ice at the staff gauge;
- (c) Interpolation error is due to inexact evaluation of the position of the index with reference to the two adjoining scale marks between which the index is located;
- (d) Observation error is similar to the reading error and is attributed to neglect or incompetence of the observer;
- (e) Error due to the negligence of one or several variables needed to determine the measured value (for example, assuming a unique stage-discharge relationship during periods of unsteady flow when slope as well as stage is a significant determinant of discharge);
- (f) Hysteresis (definition under 2.3.3.2);
- (g) Non-linearity error is that part of error whereby a change of indication or response departs from

proportionality to the corresponding change of the value of the measured quantity over a defined range;

- (h) Insensitivity error arises when the instrument cannot sense the given change in the measured element;
- (i) Drift error is due to the property of the instrument in which its measurement properties change with time under defined conditions of use, for example, mechanical clockworks drift with time or temperature;
- (j) Instability error results from the inability of an instrument to maintain certain specified metrological properties constant;
- (k) Out-of-range error is due to the use of an instrument beyond its effective measuring range, lower than the minimum or higher than the maximum value of the quantity, for which the instrument/installation has been constructed, adjusted, or set (for example, unexpected high water level);
- (l) Out-of-accuracy class error is due to the improper use of an instrument when the minimum error is more than the tolerance for the measurement.

2.3.3.5 Secondary errors of measurement

Hydrological observations are often computed from several measured components. For example, discharge at measuring structures is computed as a function of a discharge coefficient, characteristic dimensions and head. For estimating the resultant uncertainty, the Gauss error transfer (propagation) theory can be applied.

Resultant uncertainty is often referred to as overall uncertainty, which can be calculated from the uncertainties of the individual components if the errors of the individual components are assumed to be statistically independent.

If a quantity, Q , is a function of several measured quantities, x , y and z , the resultant uncertainty, e_Q , in Q due to uncertainties, e_x , e_y and e_z , in x , y and z , respectively, should be evaluated by the simplified equation of the transfer (propagation):

$$(e_Q)^2 = \left(\frac{\partial Q}{\partial x} e_x \right)^2 + \left(\frac{\partial Q}{\partial y} e_y \right)^2 + \left(\frac{\partial Q}{\partial z} e_z \right)^2 \quad (2.6)$$

where $\partial Q/\partial x$, $\partial Q/\partial y$ and $\partial Q/\partial z$ are the partial differentials of the function expressing explicitly the relationship of the dependent variable with the independent variables.

In hydrological measurements, it is very rare that a measurement can be repeated under the same conditions in the field. The standard deviation should therefore be determined by using data of changing variables as in the case of a discharge rating curve.

The standard error of estimate:

$$s_e = \left(\frac{\sum d^2}{n - 2} \right)^{1/2} \quad (2.7)$$

of the mean of observations is extremely important for characterizing the stage-discharge relationship, which needs special treatment because the relationship is not linear, but approximately logarithmic. It is an estimate of the accuracy of the computed mean relationship in a regression and, therefore, it is the range within which the true mean would be expected to lie (Figure I.2.4).

For small samples, it could be useful to have a corrected standard error of estimate, obtained by multiplying s_e by $\left(\frac{n}{n-2} \right)^{1/2}$, resulting as:

$$s_{mr} = \frac{s_e}{\sqrt{n}} \quad (2.8)$$

2.3.3.6 Characterization of instruments and methods of observation

The accuracy of a measuring instrument can be characterized by an uncertainty at a given value, corresponding to a maximum or minimum measurable value. The accuracy of an instrument without a reference value can be misunderstood or misinterpreted. The instrument accuracy is in many cases only one component of the overall accuracy of the measurement.

For characterization of uncertainty, the 95 per cent confidence level is commonly used. That is, in 5 per cent of the cases, the error could be outside the stated confidence interval. According to the *Technical Regulations* (WMO-No. 49), Volume III, measurement uncertainties should be reported in one of the following forms:

- (a) Uncertainties expressed in absolute terms:
Measured value of hydrological elements, for example, discharge: $Q = \dots$
Random uncertainty: $(e_r)_{95\%} = \dots$
- (b) Uncertainties expressed in percentage terms:
Measured value of the hydrological elements $Q = \dots$
Random percentage uncertainty $(e_r)_{95\%} = \dots\%$

In practice, uncertainties of measurements are given in a form where uncertainty is expressed as a ratio (or percentage) of Q_m , the measured value. For example, in the case of $(e_r)_{95\%} = 10\%$, $Q_m \pm 0.10 Q_m$ will contain the true value of Q 95 per cent of the time. In this case, the uncertainty is formulated by assuming average measurement conditions.

2.3.3.7 Recommended accuracy of hydrological measurements

The recommended accuracy depends mainly on the anticipated use of the measured data (the purpose of the measurement), on the potentially available instruments and on the available financial resources. Therefore, it cannot be a constant value. Rather it should be a flexible range. The recommended accuracy levels are tabulated in Table I.2.5 as a general guidance for instruments and methods of observation. In many countries, national standards regulate the required accuracies.

2.3.4 Calibration of instruments

One of the major sources of error, as stated above, is due to change in measurement characteristics of the instruments. Hydrological instrumentation comprises a large variety of mechanical, electro-mechanical and electronic devices. Mechanical instruments such as current meters or anemometers provided by reputable manufacturers are made with precision dies and are usually supplied with a factory calibration table. The factory calibration will, of course, only apply if the instrument is not damaged in use and is properly maintained. Many national hydrological agencies operate facilities to verify factory calibrations and international standards for the manufacture and calibration of, for example, current meters.

Increasingly, there is a trend towards replacing mechanical devices with electronic ones. Although they are more reliable than mechanical devices, they usually are not repairable in the field and must simply be substituted for a replacement device. Electronic instrumentation poses particular problems for hydrological agencies that may be making a transition from electromechanical devices to electronic ones as the calibration issues may be quite different. Calibration of an electronic instrument may drift due to temperature or pressure changes, or solid-state sensors may become fouled during use. It is essential that instruments be designed to function in the range of conditions that are likely to occur at the data-collection site. Some instruments have built-in calibration checks and it is important that these be used.

Table I.2.5. Recommended accuracy (uncertainty levels) expressed at the 95 per cent confidence interval

Precipitation (amount and form)	3–7%
Rainfall intensity	1 mm h ⁻¹
Snow depth (point)	1 cm below 20 cm or 10% above 20 cm
Water content of snow	2.5–10%
Evaporation (point)	2–5%, 0.5 mm
Wind speed	0.5 m s ⁻¹
Water level	10–20 min
Wave height	10%
Water depth	0.1 m, 2%
Width of water surface	0.5%
Velocity of flow	2–5%
Discharge	5%
Suspended sediment concentration	10%
Suspended sediment transport	10%
Bed-load transport	25%
Water temperature	0.1–0.5°C
Dissolved oxygen (water temperature is more than 10°C)	3%
Turbidity	5–10%
Colour	5%
pH	0.05–0.1 pH unit
Electrical conductivity	5%
Ice thickness	1–2 cm, 5%
Ice coverage	5% for $\geq 20 \text{ kg m}^{-3}$
Soil moisture	$1 \text{ kg m}^{-3} \geq 20 \text{ kg m}^{-3}$

Notes:

- When a range of accuracy levels is recommended, the lower value is applicable to measurements under relatively good conditions and the higher value is applicable to measurements under difficult situations.
- Obtaining the recommended accuracy of precipitation measurements, 3–7 per cent, will depend on many factors, including gauge characteristics. For gauges having their orifice above the ground, the gauge catch deficiency is strongly determined by wind speed and precipitation type. The catch deficiency for light snow falling during strong wind can for example be 50 per cent or more.

2.4 DESIGN AND EVALUATION OF HYDROLOGICAL NETWORKS

2.4.1 General concepts of network design

A hydrological data network is a group of data-collection activities that is designed and operated to address a single objective or a set of compatible objectives. Frequently, the objectives are associated with a particular use that is anticipated for the data being collected in the network – for example, for a water resources assessment, a development plan, or a project design. A particular hydrological station

or gauge may be included in more than one network if its data are being used for more than one purpose. In most parts of the world this is more commonly the case than not. Alternatively, a single network may consist of several types of station or gauge if they are all contributing information to the network's objective. For example, both raingauges and stream gauges might be included in a flood forecasting network.

The term network is frequently used in a less rigorous sense. It is often possible to hear of surface-water network, groundwater network, precipitation

network, or water-quality network when the speaker is referring to an aggregation of gauges and stations that have no coherence in their objectives. Data-collection sites included in a network under this looser definition may even have disparate uses for the data being collected. This disparity of usage is more than just a semantical oddity. It can cause confusion and false expectations when network analysis and design are being discussed among programme managers and hydrologists.

A network design could be based on a maximization of the economic worth of the data that are to be collected. However, such is not the case in the real world. Generally, in water resources decision-making, the economic impacts of hydrological data are never considered. Decisions are made based on the available data; the option of delaying the decision to collect more data is not explored, or deemed unacceptable. However, several examples of exceptions to this general rule are contained in the *Cost–benefit Assessment Techniques and User Requirements for Hydrological Data* (WMO-No. 717) and in the *Proceedings of the Technical Conference on the Economic and Social Benefits of Meteorological and Hydrological Services* (WMO-No. 733). A review of the hydrometric network in one Canadian province indicated that the cost–benefit ratio of the existing provincial network was 19 and that the network could be tripled in size to maximize economic benefits (Azar and others, 2003). Even in nations with very dense hydrometric networks, such as the United Kingdom, economic analysis inevitably demonstrates that benefits of hydrometric networks exceed the cost (CNS, 1991). Nonetheless many countries suffered considerable reductions in their hydrological networks in the 1980s and 1990s as a consequence of budget reductions for monitoring agencies (Pearson, 1998). For example, network reductions in Canada, Finland, New Zealand and the United States of America were 21, 7, 20 and 6 per cent, respectively. Network reductions, with rare exceptions such as New Zealand, continue.

In lieu of complete economic analyses, network designs are usually based on surrogate measures of the economics or on guidance such as that presented subsequently in this chapter.

2.4.1.1 Definition of network design

A complete network design answers the following questions pertaining to the collection of hydrological data:

- (a) What hydrological variables need to be observed?

- (b) Where do they need to be observed?
- (c) How often do they need to be observed?
- (d) What is the duration of the observation programme?
- (e) How accurate should the observations be?

To answer these questions, network design can be conceptualized as a pyramid, as shown in Figure I.2.5. The base of the pyramid is the science of hydrology. Without a thorough understanding of the hydrological setting of the area in which the network is to be established, there is little chance that the resulting network will generate information in an effective manner. Hydrological understanding comes from both education and experience, but there is no substitute for experience when initiating a hydrological network in an area where little or no historical data are available.

The right-hand side of the pyramid deals with quantitative methods for coping with hydrological uncertainty. Because of measurement errors and errors caused by sampling in space and time, there will always be hydrological uncertainty. Perfect hydrological information can never exist. Probabilistic descriptions of these errors are the most effective means of dealing with the resulting uncertainty. Probability theory provides the theorems and the language for doing so and also yields the understanding that is necessary for appropriate use of the tools of statistics. In Figure I.2.5, statistical tools are represented by sampling theory and by correlation and regression analyses, which are commonly used in quantitative network-design approaches. However, there are many other branches of statistics that may be found useful in network analysis and design. The capstone of uncertainty is Bayesian analysis, which pertains to the level of uncertainty in the descriptions of

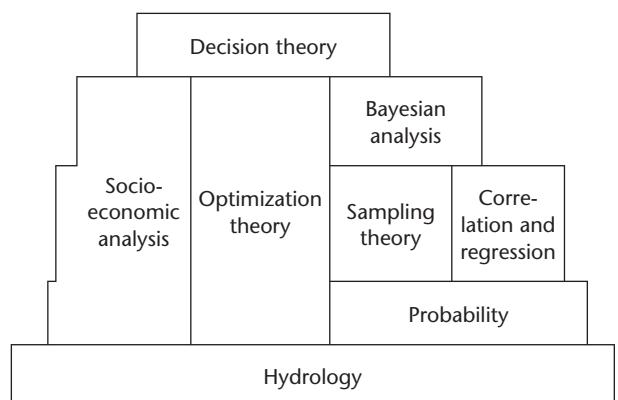

Figure I.2.5. The basic building blocks of network design

hydrological uncertainty. In other words, the probabilistic descriptions of uncertainty, based on statistics of finite samples of hydrological data, are uncertain in themselves. Reduction of uncertainty about uncertainty is a key aspect of taking full advantage of the information contained in the data that the network will generate.

The column in the middle of the structure, labelled optimization theory, is often included taxonomically as a part of socio-economic analysis. However, even in the absence of socio-economics, the optimization theory is often used in hydrological network design. Thus, it is included here as a separate component of the structure. A suite of mathematical programmes, each with its own utility and shortcomings, comprises optimization theory, which is often referred to as operations research. The context of the network-design problem determines which, if any, of the mathematical programmes can be used in a given situation. Often, the choice between two or more network designs must be made on the basis of judgement because appropriate optimization tools either do not exist or are too consuming of computer resources to be efficient.

Atop the pyramid is decision theory, which is a formal mechanism for integrating all of the underlying components. The application of decision theory in network design is not required – it is not even possible in most circumstances. However, an understanding of its pretexts and premises can make a network designer more cognizant of the impacts of his or her final decisions.

The left-hand side of the pyramid represents a rather amorphous group of technologies under the heading of socio-economic analysis. In addition to social sciences and economics, this part of the network-design structure also encompasses policy science and even politics. The latter plays a very important role in the realization of the potential benefits of water and, thus, also in the ultimate value of the data from the network. The left-hand side of the structure is the part that usually receives little rigorous consideration in the design of the data network. This is probably attributable to two causes: the subject matter is difficult to treat in an objective, mathematical way; and to do so in a substantive manner requires the synthesis of inputs from many disciplines beyond those of hydrology and water resources engineering. Thus, a network design that includes a significant socio-economic analysis will probably be both expensive and time-consuming.

Nevertheless, hydrological data-collection sites are often installed to meet pressing social needs and economic constraints with relatively little thought to meeting long-term hydrological information needs. Aside from meeting scientific needs, data-collection sites may be installed to assist water managers in responding to extreme events such as floods or droughts, allocating water supplies among competing uses, or meeting regulatory requirements. Sites operated for these latter purposes may also lead to increased hydrological understanding, but the resulting network is by no means optimized for that purpose.

2.4.1.2 Surrogate approaches

Since full-scale and complete network design is either impossible or impractical in today's world, approaches that substitute surrogate measures, objectives, or criteria are actually used to answer the questions that comprise network design. For example, a common substitution is to maximize information content from a network in lieu of optimizing the economic value of the data. Studies have shown that, if information is used properly, it can be expected to contribute to the economic worth resulting from a decision. The more information, the better the decision. However, the economic impact of information is not linearly related to its magnitude and the marginal worth of additional information decreases with the amount of information that is available. Thus, the use of this surrogate criterion can lead a Hydrological Service in the right direction if only sparse hydrological information is available, but its use can cause the collection of excess data if the region of interest already has a reasonably adequate information base.

Among the basic analytical techniques that take advantage of surrogates in the design of networks are cartographic analysis, correlation and regression methods, probabilistic modelling, deterministic modelling and regionalization techniques. Each method has particular applications and the choice depends on the limitations of available data and the type of problem under consideration. Quite often the different techniques are combined in certain applications. The *Casebook on Hydrological Network Design Practice* (WMO-No. 324) presents applications of these techniques as a means of determining network requirements. Further examples are contained in other publications (WMO/IHD Project Report No. 12; WMO-Nos. 433, 580, 806).

2.4.1.3 The basic network

The worth of the data that derive from a network is a function of the subsequent uses that are made of them. Nevertheless, many of the uses of hydrological data are not apparent at the time of the network design and, therefore, cannot be used to justify the collection of specific data that ultimately may be of great value. In fact, few hydrological data would be collected if *a priori* economic justifications were required. However, modern societies have developed a sense that information is a commodity that, like insurance, should be purchased for protection against an uncertain future. Such an investment in the case of hydrological data is the basic network, which is established to provide hydrological information for unanticipated future water resources decisions. The basic network should provide a level of hydrological information at any location within its region of applicability that would preclude any gross mistakes in water resources decision-making. To accomplish this aim, at least three criteria must be fulfilled:

- (a) A mechanism must be available to transfer the hydrological information from the sites at which the data are collected to any other site in the area;
- (b) A means for estimating the amount of hydrological information (or, conversely, uncertainty) at any site must also exist;
- (c) The suite of decisions must include the option of collecting more data before the final decision is made.

2.4.1.3.1 *The minimum network*

In the early stages of development of a hydrological network, the first step should be the establishment of a minimum network. Such a network should be composed of the minimum number of stations which the collective experience of hydrological agencies of many countries has indicated to be necessary to initiate planning for the economic development of the water resources.

The minimum network is one that will avoid serious deficiencies in developing and managing water resources on a scale commensurate with the overall level of economic development of the country. It should be developed as rapidly as possible by incorporating existing stations as appropriate. In other words, this pragmatic network will provide the basic framework for network expansion to meet future needs for specific purposes. It is emphasized that a minimum network will not be adequate for the

formulation of detailed development plans and will not meet the numerous requirements of a developed region for the operation of projects and the management of water resources.

2.4.1.3.2 *Expanding the information base*

Once the minimum network is operational, regionalized hydrological relationships, interpreted information and models can be formulated for estimating general hydrological characteristics, including rainfall and runoff at any location in the area. The basic network of observing stations should be adjusted over time until regional hydrological relationships can be developed for ungauged areas that provide the appropriate level of information. In most cases, this adjustment will result in increases in the densities of hydrological stations. However, this is not always the case. Since models are used to transfer the information from the gauged to the ungauged sites, the quality of the model is also a factor in determining the density of the basic network. If a model is particularly good, it can distil the information from the existing data better than a poorer model, and the better model would require less data to attain a given level of regional information than would the poorer one. In an extreme situation, the regional model might be so good that the level of data collection in the basic network could be reduced.

Owing to the broad dependence on the stations in the basic network, it is very important that the records from all of these stations be of high quality. Even if the installation of a station is adequate, its records may be of little value if it is not operated correctly. Continuous operation may be difficult – especially over a period of 20 years or more. A minimum network, in which stations are abandoned or irregularly observed, will have its effective density reduced and is, therefore, no longer an adequate minimum network. For that reason, care should be taken not only in establishing, but also in providing for, the continuing operation of these stations and for monitoring the reliability and accuracy of the collected records.

Economic as well as technical considerations are involved in the design and implementation of basic networks, and the number of stations requiring observation over an indefinitely long period cannot be excessive. Consequently, a sampling procedure may be adopted to maximize the cost-effectiveness of the basic network. One such approach categorizes the stations as either principal or base stations, or secondary stations. The secondary stations are operated only long enough to establish a stable

relationship, usually by means of correlations, with one or more of the base stations. A new secondary station can then be established with the equipment and funds that had been in use at the discontinued site. Records can be reconstructed at the discontinued site by means of the base-station records and the inter-station relationship. At times, it may be necessary to re-establish secondary stations if it is believed that the conditions either at the secondary site or at its related base station(s) have changed. The perpetual nature of the principal stations in the basic network provides a basis for monitoring long-term trends in hydrological conditions in the region. This is particularly important in the light of potential changes in the hydrological cycle that could be caused by land-use changes or by increases in stratospheric greenhouse gases.

2.4.1.4 Integrated network design

The hydrological cycle is a continuum, and its interconnections permit the partial transfer of information obtained in one part of the cycle to another. The efficiency of such transfers is proportional to the degree of hydrological understanding that is captured in the models that are used to route the water (and the information) between the parts of the cycle. For example, precipitation records on or near a gauged drainage basin permit the reconstruction of streamflow records during periods when the stream-gauge malfunctions if a valid precipitation-runoff model has been calibrated during times when all gauges were functioning properly. A groundwater observation well may perform a similar role for malfunctions of the stream gauge if the well is monitoring the water table of an aquifer that is directly connected to the stream.

To date, little has been done to include these interactions in network designs in an explicit manner. Ideally, the complementarity between the rain-gauges and the stream gauges that are operated in a flood-forecasting network could be used in designing a network for water resources assessment, for example. If the economic trade-offs between the two networks could be defined, they could be optimized together and peak efficiencies in information generation could be attained for both. In spite of this technological shortcoming, networks should be designed iteratively, and the outcomes of an existing design should become starting points for subsequent designs. By extension of the above example, this can be illustrated. The flood-forecasting network will probably have stream gauges and precipitation gauges at rather specific locations to meet its information needs. As the water resources

assessment will generally have less specific requirements for its information sources, it will be likely that many of the gauges of the flood-forecasting network can be incorporated into the assessment network and used as initial given conditions for its design. This iterative approach is particularly useful when designing generalized networks, like the basic network on the basis of networks, with more restrictive information demands. Networks with more restrictive demands include benchmark stations, representative basins and networks for operational purposes.

2.4.1.4.1 *Stations for operational purposes*

Stations may be established for such specific purposes as reservoir operation, irrigation, navigation, water-quality monitoring or flood forecasting. Benchmark or reference stations would also belong to this category. The length of operation of special stations is related to the purpose for which they were installed.

In some cases, the specific purpose to be served may require observations on only one particular aspect of an element, or be confined to one season of the year. For example, a hydrometric station may consist of a crest gauge for recording only the maximum flood peak or a storage gauge for measuring the total precipitation during a season. Although such stations may perform a valuable function, they do not provide the data required for general hydrological analyses. Consequently, such stations may or may not be included in a basic hydrological network.

2.4.1.4.2 *Benchmark stations*

Each country and each natural region of large countries should contain one benchmark station to provide a continuing series of consistent observations on hydrological and related climatological variables. Hydrological benchmark stations should be established in areas that are relatively uninfluenced by past or future anthropogenic changes. Since long records are the essence of a benchmark station, consideration should be given to existing stations if they meet the other requirements. The Reference Hydrometric Basin Network of Canada is one such example (Harvey and others, 1999). Climatological benchmark stations are known as reference stations.

2.4.1.4.3 *Representative basins*

A representative basin is desirable in each natural region – especially in those regions where great

economic growth is expected or where the hydrological problems are particularly difficult. In their simplest form, they permit the simultaneous study of precipitation and runoff, thus helping to make up for deficiencies in short periods of observation and low densities of minimum networks.

2.4.1.4.4 Project stations

These are stations established for a limited span of time, for specific purposes, often research oriented. Other frequent objectives may be investigations before or after physical interventions in the catchment, or for supplementing the regional coverage of the basic network. Project stations are characterized by:

- (a) Limited lifetime;
- (b) Data quality depending on purpose.

2.4.1.5 Conducting a network analysis

Figure I.2.6 lays out the steps that should be taken in conducting a review and redesign of an existing hydrological network. Such reviews should be conducted periodically to take advantage of the reduction in hydrological uncertainty brought about by the added data since the last network

analysis and to tune the network to any changes in the socio-economic environment that may have transpired. The steps of the analysis are discussed individually below.

Institutional set-up

The roles and aims of all of the organizations involved in various aspects of water resources management should be defined and identified, particularly legislative responsibilities. Communication links between these organizations should be improved to ensure coordination and integration of data-collection networks.

Purposes of the network

The purposes of the network in terms of the users and uses of the data should be identified. Data users and uses can vary temporally and spatially. There is also a need to identify potential future needs and incorporate these into the design as well.

Objectives of the network

Based on the purpose of the network, an objective or set of objectives can be established in terms of the information required. An indication of the consequences of not being able to provide this information may prove useful later.

Establish priorities

If there is more than one objective, priorities need to be set for later evaluation. If all objectives can be met within the budget, then this is not needed. However, if they cannot be met, then the lower-priority objectives may not be met fully.

Assess existing networks

Information on the existing networks should be compiled and interpreted to determine if the current networks fulfil the objectives. This may include comparisons with other basins and/or networks.

Network design

Depending on the available information and the objectives defined, the most appropriate network-design technique or techniques should be applied. This may be simple hydrological characteristics, regression relationships, or more complex network analysis using generalized least squares methods.

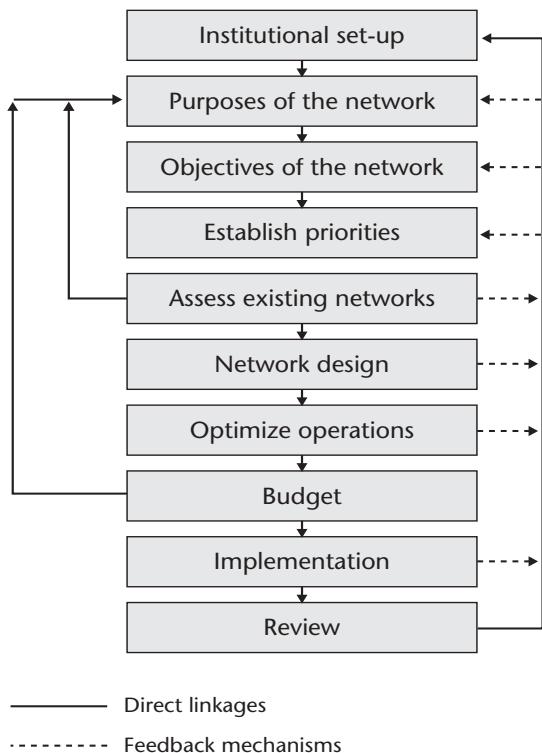

Figure I.2.6. A framework for network analysis and redesign

Optimize operations

Operational procedures account for a significant portion of the cost of data collection. This includes the types of instrument, frequency of station visits and structure of field trips. The minimum-cost operational procedures should be adopted.

Budget

Based on the identified network and operational procedures, the cost of the operation of the network can be established. If this is within the budget, the next step can be followed. If not, either additional funding must be obtained or the objectives and/or priorities need to be examined to determine where costs may be reduced. The process adopted should allow the designer to express the impact of insufficient funding in terms of not meeting objectives or reduced information and net impacts.

Implementation

The redesigned network needs to be implemented in a planned manner. This will include both short- and long-term planning horizons.

Review

Since a number of the above components are variable in time, a review can be required at the instigation of any particular component – for example, changes in users or uses, or changes in the budget. To be ready to meet such changes, a continuous review process is essential.

2.4.2 Density of stations for a network

The concept of network density is intended to serve as a general guideline if specific guidance is lacking.

As such, the design densities must be adjusted to reflect actual socio-economic and physio-climatic conditions. Computer-based mathematical analysis techniques should also be applied, where data are available, to optimize the network density required to satisfy specific needs.

As stated in 2.4.1.3.1, the minimum network is one that will avoid serious deficiencies in developing and managing water resources on a scale commensurate with the overall level of economic development and environmental needs of the country. It should be developed as rapidly as possible, incorporating existing stations, as appropriate. In other words, such a network will provide the framework for expansion to meet the information needs of specific water uses.

In the following sections, minimum densities of various types of hydrological stations are recommended for different climatic and geographic zones. These recommendations are based on the 1991 review of Members' responses regarding the WMO basic network assessment project (WMO/TD-No. 671) and are presented in Table I.2.6. However, these recommended network densities are being revisited through a study undertaken by the Commission for Hydrology and the revised recommended densities will be placed on the Website as part of the electronic version of the Guide.

It is impossible to define a sufficient number of zones to represent the complete variety of hydrological conditions. The simplest and most precise criterion for the classification of zones would be on the basis of the areal and seasonal variation of rainfall. Each country could present a good map of annual precipitation and a minimum network could be developed from this. However, this would

Table I.2.6. Recommended minimum densities of stations (area in km² per station)

Physiographic unit	Precipitation		Evaporation	Streamflow	Sediments	Water quality
	Non-recording	Recording				
Coastal	900	9 000	50 000	2 750	18 300	55 000
Mountains	250	2 500	50 000	1 000	6 700	20 000
Interior plains	575	5 750	5 000	1 875	12 500	37 500
Hilly/undulating	575	5 750	50 000	1 875	12 500	47 500
Small islands	25	250	50 000	300	2 000	6 000
Urban areas	–	10–20	–	–	–	–
Polar/arid	10 000	100 000	100 000	20 000	200 000	200 000

not help countries that need a network most as they have very few prior records, and the establishment of a good precipitation map is not possible. Also, the countries with very irregular rainfall distribution need to be considered as a special category. In such cases, it is not advisable to base the classification on this one characteristic.

Population density also affects network design. It is almost impossible to install and operate, in a satisfactory manner, a number of stations where population is sparse unless the stations are highly automated. Sparsely settled zones, in general, coincide with various climatic extremes, such as arid regions, polar regions or tropical forests.

At the other extreme, densely-populated urban areas need a very dense raingauge network for both temporal and spatial resolution of storms and for design, management and real-time control of the storm-drainage systems and for other engineering applications.

From these considerations, a limited number of larger zones have been defined for the definition of density norms in a somewhat arbitrary manner adopting some general rules. Six types of physiographic regions have been defined for minimum networks:

- (a) Coastal;
- (b) Mountainous;
- (c) Interior plains;
- (d) Hilly/undulating;
- (e) Small islands (surface areas less than 500 km²);
- (f) Polar/arid.

For the last type of region, it is necessary to group the areas in which it does not seem currently possible to achieve completely acceptable densities because of sparse population, poor development of communications facilities, or for other economic reasons.

2.4.2.1 Climatological stations

The following types of data are collected at a climatological station in the basic network: precipitation, snow survey and evaporation. It is understood here that evaporation or snow-measuring stations, particularly the former, will generally measure temperature, humidity and wind because these meteorological elements affect evaporation and melting.

2.4.2.1.1 Precipitation stations

If one follows certain principles of installation and use, the small number of stations in the minimum

network can furnish the most immediate needs. In general, precipitation gauges should be as uniformly distributed as is consistent with practical needs for data and the location of volunteer observers. In mountainous regions, attention must be given to vertical zonality by using storage gauges to measure precipitation at high altitudes. Precipitation gauges may be designed specifically to measure snow-water equivalent, either through the addition of shielding to reduce under-catch due to wind or through the use of pressure sensors. Periodic manual snow surveys may be used to supplement the network, but they should not be counted as part of the network.

The network should consist of three kinds of gauge:

- (a) Standard gauges – These gauges are read daily for quantity. In addition to daily depth of precipitation, observations of snowfall, the depth of snow on the ground and the state of the weather are to be made at each standard precipitation station;
- (b) Recorders – In developing networks, it is advisable to aim to have at least 10 per cent of such stations. The greatest density of recording stations should be achieved in those areas subject to intense, short-duration rainfalls. Such stations will provide valuable information on the intensity, distribution, and duration of precipitation.

For urban areas where the time resolution needed for rainfall measurements is of the order of one to two minutes, special attention should be paid to the time synchronization of the raingauges. For reliable measurements, tipping-bucket raingauges with an electronic memory (or another computer readable medium) are recommended.

In assigning priorities to locations for recording-raingauge installations, the following types of areas should be given priority: urban areas (population in excess of 10 000) where extensive drainage systems are likely to be constructed, river basins in which major river control systems are anticipated or are in operation, large areas inadequately covered by the existing network and special research projects;

- (c) Storage gauges (totalizers) – In sparsely settled or remote regions, such as in desert or mountainous terrain, storage gauges may be used. These gauges are read monthly, seasonally, or whenever it is possible to inspect the stations.

Location of precipitation gauges relative to stream-gauging stations – To ensure that precipitation data are available for extending streamflow records,

flood-forecasting purposes or hydrological analysis, coordination of the locations of the precipitation gauges with respect to those of the stream gauges is of great importance. Precipitation gauges should be located so that basin precipitation can be estimated for each stream-gauging station. These will usually be located at or near the stream gauge and in the upper part of the gauged drainage basin. A precipitation gauge should be located at the site of the stream gauge only if the observations will be representative of the general area. There can be cases in which it is desirable to locate the precipitation gauge some distance away from the stream gauge, as for instance when the stream gauge is in a narrow, deep valley.

2.4.2.1.2 *Snow surveys*

Where applicable, observations of snowfall, water equivalent of snow and depth of snow on the ground should be made at all precipitation stations in the minimum network.

The water equivalent of snow at the time of maximum accumulation is an indication of total seasonal precipitation in regions where winter thaws and winter snow melt are insignificant. In such regions, surveys of the snow cover on selected courses may be useful in estimating seasonal precipitation at points where the normal observations are unavailable. Such snow-cover surveys will also provide useful information for river forecasting and flood studies.

Snow-cover surveys are conducted by personnel equipped for sampling the accumulated snow and for determining its depth and water equivalent (3.5). The number of snow courses and their location and length will depend upon the topography of the catchments and the purposes for which the data are being collected. The full range of elevation and the types of exposure and vegetation cover in the area of interest should be considered in selecting representative courses. It is suggested that one course for 2000 to 3000 km² is a reasonably good density for less homogeneous regions, and one course for 5 000 km² in homogeneous and plain areas. However, each case must be considered on its own merits, and these generalities must not be applied indiscriminately.

In the early stages of network development, snow-cover surveys will usually be made only once a year, near the expected time of maximum accumulation. It will be desirable, later on, to extend the operation to include surveys at regular intervals throughout the snowfall season. As soon as it becomes feasible, these periodic snow surveys

should be augmented by regular measurements of snow precipitation and observations of related meteorological factors, such as radiation, soil temperature and wind velocity.

2.4.2.1.3 *Evaporation stations*

Evaporation can be estimated indirectly in the water-budget, energy-budget and aerodynamic approaches, by extrapolation from pan measurements or directly through use of eddy-correlation equipment (Chapter 4). An evaporation station consists of a pan of standard national design where daily observations of evaporation are made, together with daily observations of precipitation, maximum and minimum water and air temperatures, wind movement and relative humidity or dewpoint temperature.

Evaporation plays an important role for long-term studies of the water regime of lakes and reservoirs and for water management. In such cases, the number and distribution of evaporation stations are determined according to the area and configuration of the lakes and the climatic region or regions involved.

2.4.2.2 *Hydrometric stations*

2.4.2.2.1 *Streamflow stations*

The main objective of the stream-gauging network is to obtain information on the availability of surface-water resources, their geographical distribution and their variability in time. Magnitude and frequency of floods and droughts are of particular importance in this regard.

In general, a sufficient number of streamflow stations should be established along the main stems of large streams to permit interpolation of discharge between the stations. The specific location of these stations should be governed by topographic and climatic considerations. If the difference in flow between two points on the same river is not greater than the limit of error of measurement at the station, then an additional station is unjustified. In this context, it must also be stressed that the discharge of a small tributary cannot be determined accurately by subtracting the flows at two main stream-gauging stations that bracket the mouth of the tributary. Where the tributary flow is of special interest in such a case, a station on the tributary will be required. It will usually take its place as a secondary station in the minimum network. The streamflow stations may be interspersed with stage stations (2.4.2.2.2).

Wherever possible, the base stations should be located on streams with natural regimes. Where this is impractical, it may be necessary to establish additional stations on canals or reservoirs to obtain the necessary data to reconstruct the natural flows at the base stations. Computed flows past hydroelectric plants or control dams may be useful for this purpose, but provisions will have to be made for calibration of the control structures and turbines and for the periodic checking of such calibrations during the life of the plants.

Stations should be located on the lower reaches of the major rivers of the country, immediately above the river mouths (usually above tidal influence) or where the rivers cross borders. Stations should also be located where rivers issue from mountains and above the points of withdrawal for irrigation water. Other hydrometric stations are situated at locations, such as where the discharge varies to a considerable extent, below the points of entry of the major tributaries, at the outlets from lakes, and where large structures are likely to be built. Hydrometric stations are often established at major cities to meet a number of societal needs.

To ensure adequate sampling, there should be at least as many gauging stations on small streams as on the main streams. However, a sampling procedure for small streams becomes necessary, as it is impracticable to establish gauging stations on all of them. The discharge of small rivers is strongly influenced by local factors. In highly developed regions, where even the smallest watercourses are economically important, network deficiencies are keenly felt even on streams draining areas as small as 10 km².

Stations should be installed to gauge the runoff in different geologic and topographic environments. Because runoff varies greatly with elevation in mountains, the basic network stations must be located in such a way that they can, more or less evenly, serve all parts of a mountainous area, from the foothills to the higher regions. Account should be taken of the varying exposure of slopes, which is of great significance in rough terrain, and to land cover, which may vary with exposure and other factors. Similarly, consideration should be given to stations in districts containing numerous lakes, the influence of which can be determined only through the installation of additional stations.

2.4.2.2.2 *River stages*

Stage (height of water surface) is observed at all stream-gauging stations to determine discharge.

There are places where additional observations of water level only are needed as part of a minimum network:

- (a) At all major cities along rivers, river stages are used for flood forecasting, water supply and transportation purposes;
- (b) On major rivers, at points between stream-gauging stations, records of river stage may be used for flood routing and forecasting purposes.

2.4.2.2.3 *Lake and reservoir stages*

Stage, temperature, surge, salinity, ice formation, etc., should be observed at lake and reservoir stations. Stations should be established on lakes and reservoirs with surface areas greater than 100 km². As in the case of rivers, the network should sample some smaller lakes and reservoirs as well.

2.4.2.2.4 *Sediment discharge and sedimentation*

Sediment stations may be designed either to measure total sediment discharge to the ocean or to measure the erosion, transport and deposition of sediment within a country, basin, etc. In designing a minimum network, emphasis should be placed on erosion, transport and deposition of sediment within a country. An optimum network would contain a sediment station at the mouth of each important river discharging into the sea.

Sediment transport by rivers is a major problem in arid regions, particularly in those regions underlain by friable soils and in mountainous regions where, for engineering applications, the amount of sediment loads should be known.

The designer of a basic network must be forewarned that sediment-transport data are much more expensive to collect than other hydrological records. Consequently, great care must be exercised in selecting the number and location of sediment-transport stations. Emphasis should be placed on those areas where erosion is known to be severe. After a few years of experience, it may be desirable to discontinue sediment measurements at those stations where sediment transport no longer appears to be of importance.

Sediment-transport data may be supplemented by surveys of sediment trapped in lakes or reservoirs. Echo-sounding devices are useful for this purpose. However, information obtained in this way is not considered a substitute for sediment-transport measurements at river stations. Sediment discharge measurement and the computation of sediment load are covered in 5.5.

2.4.2.2.5 *Water-quality stations*

The usefulness of a water supply depends, to a large degree, on its chemical quality. Observations of chemical quality, for the purposes of this Guide, consist of periodic sampling of water at stream-gauging stations and analyses of the common chemical constituents. ISO Technical Committee 147 has prepared over 200 international standards pertaining to field sampling for water-quality and analytical methods.

The number of sampling points in a river depends on the hydrology and the water uses. The greater the water-quality fluctuation, the greater the frequency of measurement required. In humid regions, where concentrations of dissolved matter are low, fewer observations are needed than in dry climates, where concentrations, particularly of critical ions such as sodium, may be high.

2.4.2.2.6 *Water temperature*

The temperature of water should be measured and recorded each time a hydrometric station is visited to measure discharge or to obtain a sample of the water. The time of day of the measurement should also be recorded. At stations where daily stage observations are made, temperature observations should also be made daily. These observations, the cost of which is negligible, may provide data which are useful in studies of aquatic life, pollution, ice formation, sources of cooling water for industry, temperature effects on sediment transport, solubility of mineral constituents, or climate change.

2.4.2.2.7 *Ice cover on rivers and lakes*

Regular observations of ice cover should include the following:

- (a) Visual observations of various processes of ice formation and of ice destruction, with recording of date of first occurrence of floating ice, date of total cover, date of break-up of the ice, and date at which the ice has vanished completely. These observations should be made on a daily basis;
- (b) Simultaneous measurement of ice thickness at two or three points near each selected hydrometric station should be made once every 5 to 10 days. The location of measurement points is chosen from detailed surveys of ice cover made at the beginning of the observing period of the stations.

2.4.3 **Specific requirements for water quality**

There are several approaches to water-quality monitoring. Monitoring can be accomplished through a network of strategically located long-term stations, by repeated short-term surveys, or by the most common approach, a combination of the two. In addition to the basic objectives of the programme, the location of stations should take into account the following factors:

- (a) Existing water problems and conditions;
- (b) Potential growth centres (industrial and municipal);
- (c) Population trends;
- (d) Climate, geography and geology;
- (e) Accessibility;
- (f) Available human resources, funding, field and laboratory data handling facilities;
- (g) Inter-jurisdictional considerations;
- (h) Travel time to the laboratory (for deteriorating samples);
- (i) Safety of personnel.

The design of a sampling programme should be tested and assessed during its initial phase to ensure the effectiveness and efficiency with respect to the objectives of the study.

2.4.3.1 *Water-quality parameters*

The parameters that characterize water quality may be classified in several ways, including physical properties (for example, temperature, electrical conductivity, colour and turbidity), inorganic chemical components (for example, dissolved oxygen, chloride, alkalinity, fluoride, phosphorous and metals), organic chemicals (for example, phenols, chlorinated hydrocarbons, polycyclic aromatic hydrocarbons and pesticides), and biological components, both microbiological, such as faecal coliforms, and macrobiotic, such as worms, plankton and fish, which can indicate the ecological health of the aquatic environment.

A second classification is done according to the importance attached to the parameter. This will vary with the type of water body, the intended use of the water and the objectives of the monitoring programme. Water-quality variables are sometimes grouped into two categories:

- (a) Basic variables (Table I.2.7) (UNEP, 2005);
- (b) Use-related variables:
 - (i) Drinking water supplies;
 - (ii) Irrigation;
 - (iii) General quality for aquatic life.

A third classification that is highly relevant to sampling procedures is done according to stability:

- (a) Conservative (does not change materially with time);
- (b) Non-conservative (changes with time, but can be stabilized for at least 24 hours by appropriate treatment); or
- (c) Non-conservative (changes rapidly with time and cannot be stabilized).

The first two groups can be measured by representative water samples subsequently analysed in the laboratory. The third group needs to be measured in situ.

2.4.3.2 Surface-water quality

Sometimes the programme objectives will precisely define the best locations for sampling in a river or lake system. For example, in order to determine the effect of an effluent discharge on a receiving stream, sampling locations upstream and downstream of the discharge would be required. In other cases, both location and frequency of sampling will be determined by anti-pollution laws or by a requirement for a specific use of a water body. For example, a permit to discharge surface waters may outline details of monitoring, such as location, number of samples, frequency and parameters to analyse. Water-quality monitoring programmes may be

Table I.2.7. GEMS/Water basic variables

Water quality category	<i>GEMStat</i> parameters

GRF Essential for global river flux monitoring stations

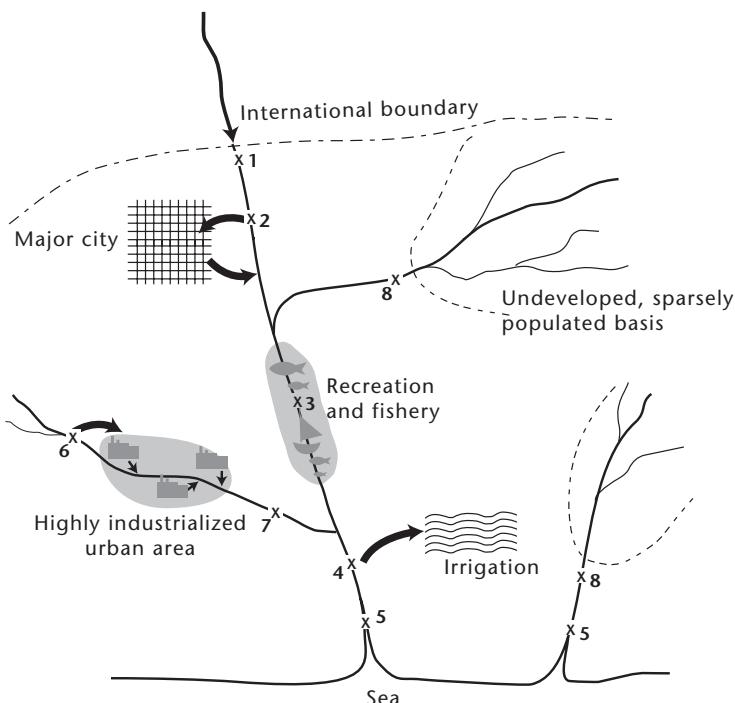

supplemented by intensive, but infrequent, special purpose water-quality surveys aimed at understanding short-term fluctuations in water-quality parameters. As well, special situations may call for water-quality surveillance, the continuous, specific measurement of selected parameters.

Sampling strategies vary for different kinds of water bodies and media, for example, water, sediment, or biota. Rivers mix completely within distances ranging from several kilometres to a few hundred kilometres of any point source of pollution. Lakes may be vertically stratified because of temperature or inflows of high-density saline water. Groundwater tends to flow very slowly, with no surface indication of the changes in its solutes taking place below.

If the objective concerns the impact of human activities on water quality in a given river basin, the basin can be separated into natural and altered regions. The latter can be further subdivided into stationary zones for instance, over periods longer than 10 years, and those in which the impact is variable, such as agricultural, residential and industrial zones. In acid-deposition studies, an important factor is the terrain sensitivity to the deposition. Figures I.2.7 and I.2.8 provide some examples of where and how sampling stations could be located to meet specific objectives on river and lake systems.

The next step in choosing sampling locations is to collect relevant information about the region to be monitored. The information sought includes geological, hydrological and demographic aspects, as well as the number of lakes and streams, size and locations of aquifers, locations of existing water-quality or stream-gauging stations, flow rates, climatic conditions in the catchment area, historical developments, present and potential municipal and industrial centres, current water intakes and waste outlets, natural salt springs, mine drainage, irrigation schedules, flow regulation (dams), present and planned water uses, stream or lake water-quality objectives or standards, accessibility of potential sampling sites (land ownership, roads and airstrips), availability of services such as electricity, and existing water-quality data. Figure I.2.9 shows the steps to be followed in selecting sampling sites. The distance downstream to the point of complete mixing is roughly proportional to the stream velocity and to the square of the width of the channel. Rivers are usually sufficiently shallow that vertical homogeneity is quickly attained below a source of pollution. Lateral mixing is usually much more slowly attained. Thus, wide swift-flowing rivers may not be completely mixed for many kilometres downstream from the input point.

Various protocols are recommended to determine representative sampling in the cross-section of the river, for example, six samples analysed in duplicate,

Station	Criteria
1	Immediately downstream of an international boundary
2	Diversion for public supply of large town
3	Important fishing, recreation and amenity zone
4	Diversion for large-scale agricultural irrigation
5	Freshwater tidal limit of major river
6	Diversion for large industrial supply
7	Downstream of industrial effluent discharges and important tributary influencing main river
8	Baseline station, water in natural state

Figure I.2.7. Monitoring site: rivers

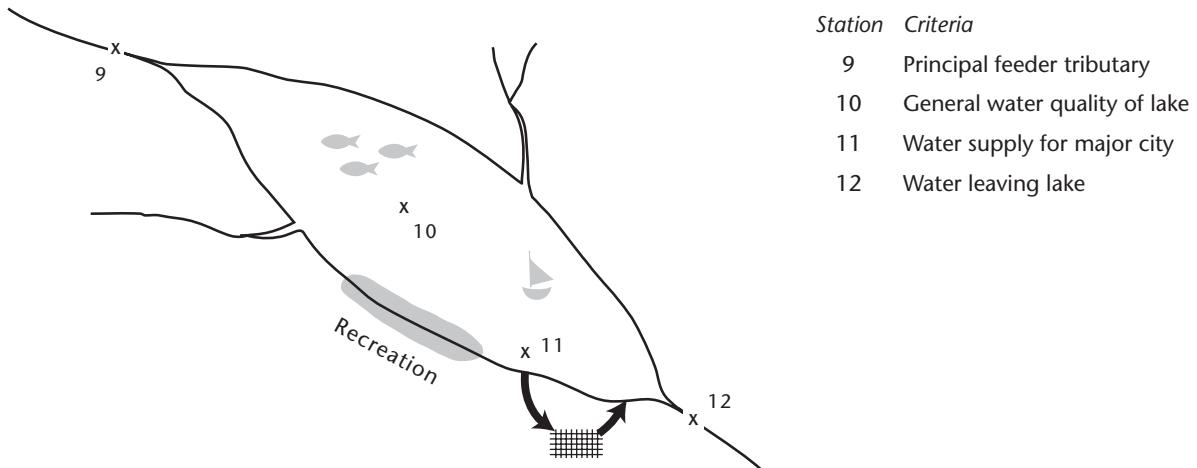

Figure I.2.8. Monitoring site: lakes

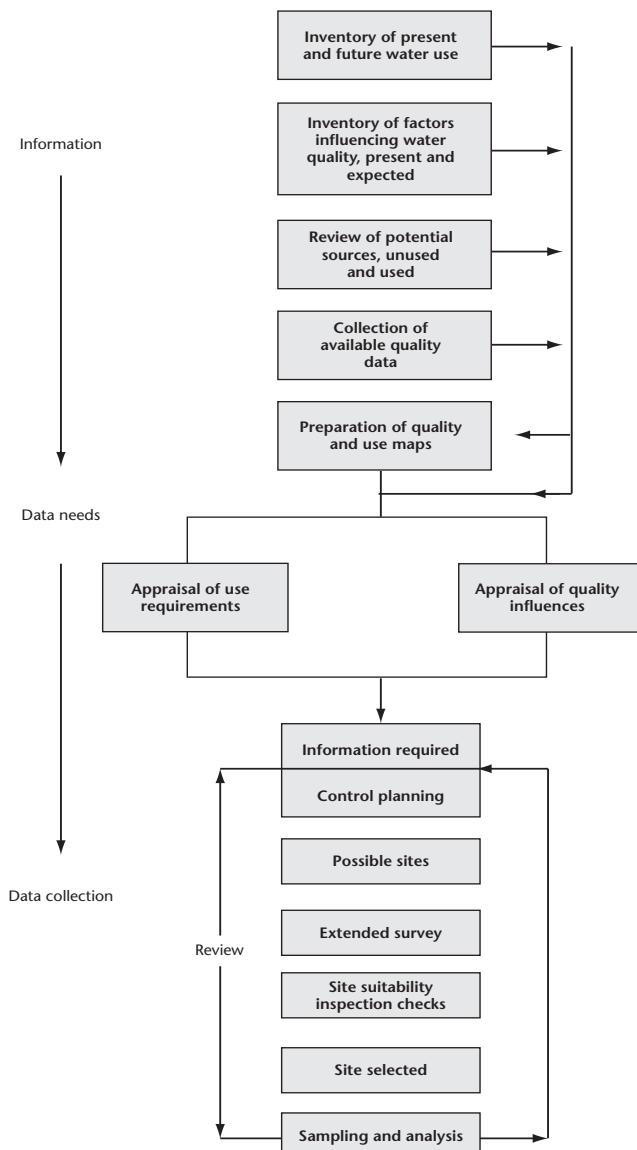

Figure I.2.9. Scheme for the selection of water quality sampling sites

at three positions across the river and two depths or mid-depth samples at the quarter points, or other equal distance points across the width of the river. If a representative sample cannot be obtained, it is advisable to select another site, either immediately upstream or downstream. The other alternative is to obtain a flow-weighted composite sample from samples collected on cross-section verticals.

Longitudinal mixing of irregular or cyclic discharges into a river will have a secondary influence on the location of a sampling site. Their effects need to be taken into account in deciding the frequency of sampling and interpreting data.

Sampling frequency depends on the purpose of the network, the relative importance of the sampling station, the range of measured values, the time variability of the parameter of interest and the availability of resources. In the absence of sufficient background information, an arbitrary frequency based on knowledge of local conditions is chosen. After sufficient data have been collected, the frequency may be adjusted to reflect the observed variability. The frequency is also influenced by the relative importance of the station and whether or not the concentrations approach critical levels for some substances measured.

For lake stations, the recommended practice is to sample five consecutive days during the warmest part of the year and five consecutive days every quarter. Special cases include temperate-zone lakes that experience stratification. These should be sampled at least six times a year, together with the occasional random sample, to cover the following periods: during open water prior to summer stratification, during mixing following summer stratification, under ice, and during the periods of snow melt and runoff. Similarly, additional samples of rivers should be taken, if possible, after storm events and during snow melt and runoff.

When parameters are plotted against time, some cyclic variation may be apparent amidst the random fluctuations. The detection of cyclic events requires a sampling interval no longer than one third of the shortest cycle time and sampling over a period at least ten times longer than the time of the longest cycle. Therefore, long-period cycles will not be verified in the initial surveys, but become apparent during the operation of the network. In order to detect the cyclic variations, some random sampling is desirable, for example, on different days of the week or different hours of the day.

2.4.3.3 Precipitation quality

In general, sampling sites should be selected to give accurate and representative information concerning the temporal and spatial variation of chemical constituents of interest. Important factors to take into consideration are prevalent wind trajectories, sources for compounds of interest, frequency of precipitation events (rain, snow, hail), and other meteorological processes that influence the deposition. There are also local criteria to be considered:

- (a) No moving sources of pollution, such as routine air, ground, or water traffic, should be within 1000 m of the site;
- (b) No surface storage of agricultural products, fuels, or other foreign materials should be within 1000 m of the site;
- (c) Samplers should be installed over flat undisturbed land, preferably grass-covered, surrounded by trees at distances greater than 5 m from the sampler. There should be no wind-activated sources of pollution nearby, such as cultivated fields or unpaved roads. Zones of strong vertical eddy currents, eddy zones leeward of a ridge, tops of wind-swept ridges and roofs of buildings, particularly, should be avoided because of strong turbulence;
- (d) No object taller than the sampler should be within 5 m of the site;
- (e) No object should be closer to the sampler than a distance of 2.5 times the height by which the object extends above the sampler. Particular attention must be given to overhead wires;
- (f) The collector intake should be located at least 1 m above the height of existing ground cover to minimize coarse materials or splashes from being blown into it;
- (g) Automatic samplers require power to operate lids and sensors, and in some cases for refrigeration in the summer and thawing in the winter. If power lines are used, they must not be overhead. If generators are used, the exhaust must be located well away and downwind from the collector;
- (h) To address issues on a continental scale, sites should preferably be rural and remote, with no continuous sources of pollution within 50 km in the direction of the prevalent wind direction and 30 km in all other directions.

It may not be possible to meet all of these criteria in all cases. The station description should refer to these criteria and indicate the exact characteristics of each location chosen as a sampling site.

In the case of large lakes, the precipitation over the lake may not be as heavy as along the shores and the proportion of large particles may be smaller. In order to sample in the middle of a lake, the sampler can be mounted on a buoy, rock, shoal or small island.

Event sampling is the preferred method for sampling precipitation. Each rain shower, storm or snowfall constitutes an event. The analysis of event-precipitation samples enables pollutants associated with a particular storm to be determined, and a wind-trajectory analysis can determine probable sources. However, this sampling regime is very sensitive. The same statistical considerations concerning frequency of sampling apply here as for surface-water sampling.

2.4.3.4 Sediment quality

Most of the selection criteria outlined in previous sections also apply to sampling for sediment. Therefore only additional special recommendations will be described here.

For rivers where sediment-transport data are required, it is necessary to locate the sampling sites near a water quantity gauging station so that accurate stream discharge information is available at all times. Sampling locations immediately upstream from confluences should be avoided because they may be subjected to backwater phenomena. In streams too deep to wade, locate sampling sites under bridges or cableways. When sampling from bridges, the upstream side is normally preferred. Sampling in areas of high turbulence, such as near piers, is often unrepresentative. Attention also must be paid to the accumulation of debris or trash on the piers, as this can seriously distort the flow and hence the sediment distribution. An integrated sample obtained by mixing water from several points in the water column according to their average sediment load can be considered as a representative sample as long as there is good lateral mixing.

The best places to sample bottom deposits in fast-flowing rivers are in shoals, at channel bends and at mid-channel bars or other sheltered areas where the water velocity is at its minimum.

Sampling sites should be accessible during floods, since sediment-transport rates are high during these times.

For identification of peak pollution loads in rivers, two cases must be considered:

- (a) For pollution from point sources, sampling should be done during low-flow periods, when pollution inputs are less diluted;
- (b) When pollutants originate from diffuse sources such as runoff from the land of agricultural nutrients or pesticides, sampling must be focused on flood periods during which the pollutant is washed out of the soil.

If one of the objectives is to quantify the transport of sediment in the river system, it should be noted that peak concentrations of sediment do not necessarily correspond with times of peak flow. Also, a series of high flow rates will lead to progressively lower sediment peaks – an exhaustion effect arising from the depletion of material available for re-suspension.

For lakes, the basic sampling site should be located at the geographic centre of the lake. If the lake is very large (area > 500 km²), several base stations may be needed. If various sediment types must be sampled, then data from acoustic surveys (echosounders) can be used both to identify the type of surficial material (sand, gravel or mud) and to indicate the presence of layering below the surface. Secondary sampling sites should be located between the base station and major tributary inlets or pollutant sources. A common strategy is to place points down the long axis of the lake with occasional cross-lines. Three to five stations should usually give a good approximation to the sediment quality of an average size lake. For statistical validity, however, a larger number of sampling sites will probably be required.

Sampling frequency in lakes is affected by the generally low concentrations of suspended sediment. Sediment traps should be operated during periods of maximum and minimum algal productivity and at times of high input of sediment from rivers.

Repeat sampling of bottom sediments in lakes needs to take into account the rates of sediment accumulation. Basins in cool temperate climates often have accumulation rates in the order of 0.1–0.2 mm per year. A resampling period of five years would then be too soon to provide worthwhile new information, unless the presence of a new pollutant is to be tested.

2.4.3.5 Groundwater quality

A great deal of hydrogeological information may be necessary to plan the sampling strategy for aquifers. Water levels, hydraulic gradients, velocity and direction of water movements should be known.

An inventory of wells, boreholes and springs fed by the aquifer should be drawn up, and details of land use should be recorded.

Groundwater samples are taken from drainage water, open wells and drilled wells. Wells should be sampled only after they have been pumped long enough to ensure that a fresh sample has been obtained. This is particularly necessary where a well has a lining subject to corrosion.

An existing well is a low-cost choice, although wells are not always at the best location or made of non-contaminating materials. A well that is still in use and pumped occasionally is preferable to one that has been abandoned. Abandoned or unused wells are often in poor condition with damaged or leaky casings and corroded pumping equipment. It is often difficult to measure their water levels, and they may be safety hazards.

Changes in groundwater quality can be very slow and are often adequately described by monthly, seasonal or even annual sampling schedules.

2.4.4 Operational data acquisition networks

Many types of hydrological forecasts are compiled on the basis of data from networks. Information may include measurements, as well as details of the operation of water-management and flood-protection works. A forecast system should make use of data from the basic network (2.4.1.3) as far as possible. The scope of the forecast network is determined by:

- (a) User demands for forecasts at specified locations and for current information on the status of water bodies;
- (b) The network density needed to describe the hydrological characteristics and the dimensions of water bodies;
- (c) The technology for data transmission to the forecast centre;
- (d) The representativeness of the observations;
- (e) The media for issuing forecasts.

The information on water-management operations should be organized to fit in with the normal operational routines of the water-management agencies that supply the information.

A schedule of reports transmitted to the forecast centre by non-automatic monitoring stations should be drawn up, and the reports should be classified according to whether they are regularly or occasionally transmitted. The regular reports should

include daily information on water levels, discharge and temperature and, where appropriate, ice phenomena, as well as observations every 5 or 10 days on ice thickness, snow depth and water equivalent. The occasional reports contain emergency information on significant changes in the regime of water bodies and operational control strategies, as well as specially requested reports that are needed to define the development of particular hydrological phenomena.

The *Casebook on Hydrological Network Design Practice* (WMO-No. 324) gives examples of spatial densities for various hydrological variables and the general principles for determining them based on the time and space variability.

2.4.5 Network-strategy options

In addition to seeking to improve representativeness of existing surface-water data networks, Hydrological Services should develop more comprehensive monitoring strategies. For selected basins, the hydrometric data-collection activities need to be integrated with sediment, water quality, meteorology and aquatic-habitat programmes (2.4.1.4). For example, concerns for sediment-associated contaminant transport require knowledge of the source, pathways and fate of fine particles. This requires an understanding of both the flow and sediment regimes. Whether for the interpretation of concentrations or for calculating contaminant loadings, such integrated monitoring requires close coordination at all stages from planning to reporting.

Integrated planning of related data networks should be developed to maximize the effectiveness of all water-data programmes. Significant efforts are required to define network needs from many different perspectives, and, ultimately, to coordinate the data collected on a watershed basis so that adequate water data, that is, precipitation, runoff, groundwater and water quality, are available to meet future needs.

Present monitoring programmes can be enhanced by the use of supplementary studies. For example, river studies of sediment sources and morphologic change (Church and others, 1989; Carson, 1987) supplement regular programme data to determine the river behaviour. This knowledge, which is not acquired from monitoring studies alone, is being used for fisheries management, river-engineering studies and water-quality studies.

On a different scale, water-quality considerations are increasingly important to urban drainage design.

The design of appropriate monitoring programmes should consider short-interval sampling, integrated precipitation and runoff monitoring, and extremely rapid response times if the data are to be useful. These conditions are quite different from those covered by standard monitoring procedures. The use of computer models is an additional strategy for enhancing the information derived from water-monitoring activities. In certain circumstances, monitoring-network designs can be improved by the use of models.

2.5 DATA COLLECTION

2.5.1 Site selection

Once the network design phase has been completed, the operational requirements have established the general location of the data-collection sites, and the types of instrumentation have been identified, the best specific site in the general location is selected to meet the requirements of the instrumentation as outlined in subsequent chapters of this Volume (5.3.2.1 and 5.4.2). Modifications to the site may be necessary to ensure the quality of the data, for example, clearing and control stabilization.

When a site has been selected and the instrumentation has been installed, two types of data will be collected at the site: descriptive details of the site and its location, and the hydrological observations that it has been established to measure. Once established, the installation should be operated and maintained to its predetermined standard. In general, this involves the execution of an adequate schedule of inspection and maintenance to ensure continuity and reliability of data, and the development of routine check measurements and calibrations to ensure data of the required accuracy.

2.5.2 Station identification

Two aspects should be considered to ensure the historical documentation of details of a data-collection site: the institution of an identification system and the archival of descriptive information.

2.5.2.1 Identification of data-collection sites

Every permanent site should be given a unique identifier that will be used to denote all data and other information pertinent to the site. Such identifiers are usually numeric, but they may also be alphanumeric.

Frequently, more than one service or agency may be operating data-collection sites in one particular region or country. The acceptance by all parties of a single, unique system of site identification will facilitate data interchange and the multiparty coordination of data-collection activities. The region chosen should be determined by drainage basin(s) or climatic zones, and part of a site's identification should reflect its location in the region.

The site identification can be simply an accession number, that is, a sequential number assigned as stations are established. For example, site identification in the Canadian National Water Quality Data Bank, NAQUADAT, represents a sophisticated system designed for computer processing. It has a 12-digit alphanumeric code, which is the key element in storing and retrieving data in the computer system. This number is composed of several subfields (UNEP/WHO, 1996), as follows:

- (a) Type of water – a two-digit numerical code indicating the type of water sampled at any given location, such as streams, rivers and lakes, or precipitation. The meaning of this code has been extended to include other types of aquatic media. A list of all currently assigned codes is given in Table I.2.8;
- (b) Province, basin and sub-basin – three pairs of digits and letters identifying the province, basin and sub-basin;
- (c) Sequential – a four-digit number assigned usually by a regional office.

For example, station number 00BC08NA0001 indicates that the sampling site is on a stream, in the province of British Columbia, in basin 08 and in sub-basin NA, and the sequence number is 1. Station number 01ON02IE0009 is on a lake, in the province of Ontario, in basin 02 and in sub-basin IE and the sequence number is 9.

WMO has accepted a coding system for station identification (Moss and Tasker, 1991) that is similar to (b) and (c) of the NAQUADAT system.

Another well-known coding system for sampling points is the River Mile Index used by the Environmental Protection Agency of the United States as part of the STORET system. In this system, the location of a sampling point is defined by its distance and hydrological relationship to the mouth of a river system. It includes major and minor basin codes, terminal stream numbers, the direction and level of streamflow, the mileages between and to confluences in the river system, and a code to identify the stream level on which the point is located.

2.5.2.2 Descriptive information

In many instances the value of the data will be enhanced if the user can relate it to the details of the history of its collection as part of the routine production of metadata. To this end, a station registration file should record the details of each station. The level of detail will of course vary with the parameter monitored. Typical information would

include the station name and location details, the station type, the associated stations, establishing/operating/owner authorities, the elevation details, the frequency of observation, the operating periods and the details of installed equipment. Additional items specific to the station type should also be included. Selected information from this text file should be attached routinely to any data output (Chapter 10).

A historical operations file of more detailed information should also be prepared for release as required (Chapter 10). Again, the level of detail will vary with the type of observations being recorded. A stream station may include details such as climate zone and rainfall and evaporation notes, geomorphology, landforms, vegetation, land use and clearing, and station details. Typical components of such a file would include the station description, a detailed sketch of the site, a map showing the location of the site in the region, and a narrative description of the site and region. Some examples of the format of such files can be found in the UNEP (2005) and Environment Canada (1983) publications. Figure I.2.10 is an example of one format.

2.5.2.2.1 Station description

An accurate description of the sampling location includes distances to specific reference points. It is important that these reference points be permanent and clearly identified. For example, "5 metres north-west of the willow sapling" is a poor designation for a data site. An example of a useful description is "30 metres downstream from Lady

Aberdeen Bridge (Highway 148), between Hull and Pointe Gatineau and 15 metres off the pier on the left side looking downstream". If hand-held global positioning devices are available, the geographic coordinates of the sampling location should be determined and recorded on the station description. The dates that the station was first established and that data collection was commenced should also be recorded.

For streamflow and water-quality data stations, location information should also include descriptions of the water body above and below the station. These should include water depths, a description of the banks on either side of the water body and the bed material. A description of the water body should include any irregularities in morphology that might affect the flow of water or its quality. Such irregularities may include a bend in a river, a widening or narrowing of the channel, the presence of an island, rapids or falls, or the entry of a tributary near the station. A description of the banks should mention slope, bank material and extent of vegetation. Bed or sediment material may be described as rocky, muddy, sandy, vegetation-covered, etc. Station-location descriptions

Tp Region Established April 19 78 Distance from base to station 1.5 km Distance from station to site of analysis 17 km Location of station with respect to towns, bridges, highways, railroads, tributaries, islands, falls, dams, etc. <u>30 m downstream of Lady Aberdeen bridge (Highway 148)</u> <u>between Hull and Pointe Gatineau and 15 m off pier on</u> <u>left side (looking downstream)</u> Description and location of nearby hydrometric installations: <u>Baskatong dam about 190 km upstream</u> <u>Farmers rapids about 25 km upstream</u>									
SPECIMEN									
OBSERVATIONS									
Natural conditions and/or control installations which may affect flow regimes: <u>Baskatong dam</u> <u>Farmers rapids</u>									
Sources of chemical or physical inputs: <u>Logs, local sewage input</u>									

Figure I.2.10. Station-location forms

should mention seasonal changes that may hinder year-round data collection. Additional information in the case of lakes could include surface area, maximum depth, mean depth, volume and water residence time.

Additional information about conditions, either natural or man-made, which may have a bearing on the data should be recorded. Past and anticipated land disturbances and pollution sources should be mentioned, for example, forest fires, road construction, old mine workings, and existing and anticipated land use.

2.5.2.2.2 *Detailed sketch of station location*

A sketch of the location and layout of the station (including distances expressed in suitable units) with respect to local landmarks and permanent reference points, such as benchmarks, should be prepared (Figure I.2.11). Sampling or measuring sites and equipment locations should be prominently shown on the sketch.

2.5.2.2.3 *Map*

A large-scale map (Figure I.2.12) that locates the site with respect to roads, highways and towns should be included. The combination of the map and the sketch of the station location should provide complete location information. An investigator travelling to the site for the first time should have enough information to locate the station confidently and accurately.

2.5.2.2.4 *Coordinates*

Geographical coordinates are recorded as latitude and longitude and, in addition, coordinates may be recorded in other reference systems such as

universal transverse mercator (UTM) coordinates or legal land descriptions. If the site is on a stream, its distance upstream from a reference point, such as a reference station or a river mouth should be recorded. National grid references, if available, should also be provided. For the international GLOWDAT (that is, GEMS/WATER data bank (UNEP, 2005) station), one entry is the WMO code for the octant of the globe for the northern hemisphere: 0, 1, 2 and 3 for 0–90°W, 90–180°W, 180–90°E and 90–0°E, respectively (WMO-No. 683). Correspondingly, for the southern hemisphere the codes are: 5, 6, 7 and 8 for 0–90°W, 90–180°W, 180–90°E and 90–0°E (WMO-No. 559).

Latitude and longitude values should be obtained using a global positioning system or, if that is not possible, from 1:50 000 or 1:250 000 topographical maps. Points on a 1:250 000 map can be located to about ±200 m and on a 1:50 000 scale to about ±40 m (WMO-No. 559). If available, navigational charts can be used to provide more accurate values than the topographical maps.

2.5.2.2.5 *Narrative description*

For streamflow and water-quality sites, it is recommended that the narrative description begin with the name of the river, stream, lake, or reservoir, followed by its location (for example, upstream or downstream) and its distance (to 0.1 km or better) from the nearest town, city, important bridges, highways or other fixed landmarks. The name of the province, territory or other geopolitical division should also be included.

Information concerning changes at the site, including instrumentation changes, should be added to the narrative description to provide a historical description of the site and the region that

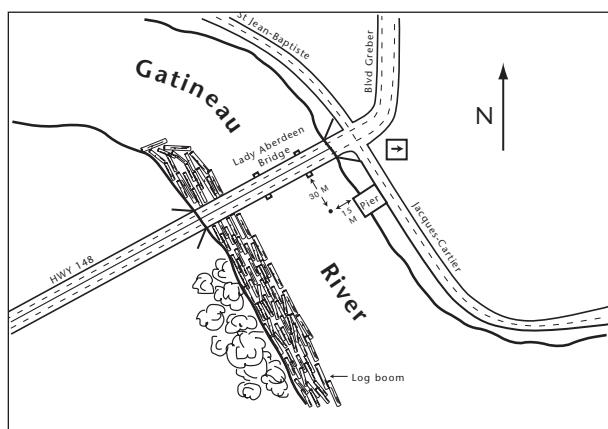

Figure I.2.11. Sketch of station layout

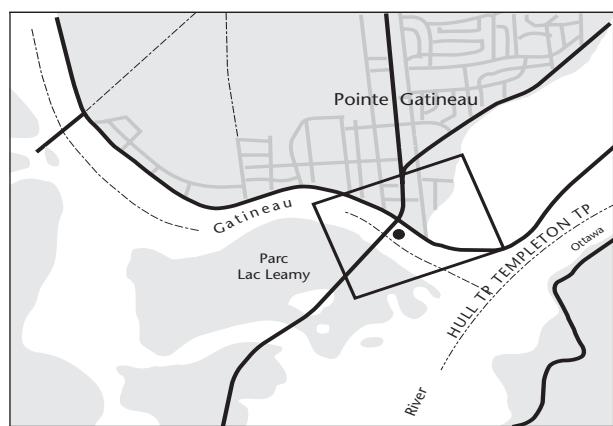

Figure I.2.12. Station-location map

it represents. Chapter 10 contains a suggested format for such information.

2.5.3 Frequency and timing of station visits

The frequency and timing of readings and thus visits to the site should be determined by the anticipated data usage and should be adequate to define the observations over time. Station visits will thus be for purposes of observation or collection of data and for maintenance of the site.

When the variable of interest at the site is changing rapidly, visits to manual stations must be more frequent if a valid record is to be maintained. Under such conditions, it may be more efficient to install automatic recording equipment or real-time transmission if funds and trained staff are available. This applies particularly where more frequent observations are desirable for hydrological purposes during storms and flood periods, as well as in tidal reaches of rivers.

2.5.3.1 Manual stations

There is considerable merit in encouraging the taking of observations at climatological stations at specified synoptic hours. WMO recommends (WMO-No. 544) that the time at which three-hourly and six-hourly weather observations are taken at synoptic stations are 0000, 0300, 0600, 0900, 1200, 1500, 1800 and 2100 universal time coordinated (UTC). In most countries, such stations are the key stations of the meteorological and climatological observation programmes. If the observer is to take three observations per day, the synoptic hours most conveniently related to normal times of rising and retiring and that nearest noon should be specified. For stations at which only one or two observations per day are taken, it should be possible to select synoptic hours for the observations.

It is recommended that all observers making only one observation per day should have a common observation time, preferably in the morning.

Some streams, for example small mountain-fed streams, may experience diurnal fluctuations in water levels during some seasons. Stage observations should initially be made several times a day at new stations to ensure that a single reading is an adequate representation of daily water level. Also, small streams may exhibit "flashy" behaviour in response to rain storms. Additional stage readings should be obtained during these times to adequately define the hydrograph. Stage observations should

also be made at the time of water-quality sampling.

While it is desirable to have regular observations at synoptic hours, in some cases this will not be possible. In these cases, it is important that observations be taken at the same time each day and that this time be recorded in UTC or local standard time using 24-hour clock designations. If "summer time" (daylight saving time) is introduced for part of the year, arrangements should be made to have observations taken at the same hour, by UTC, as in the period prior to and following "summer time".

The designated time of climatological observations should be the end of the time at which the set of observations is taken at a station. The set of observations should be taken, if possible, within the 10-minute period prior to the stated observational time. However, it is important that the actual time of observation be recorded carefully, whether the observation is taken at a standard time or not. In tidal reaches of rivers, the times of observation should be related to the tidal cycle.

2.5.3.2 Recording stations

The frequency and timing of visits to recording stations will be constrained by the length of time that the station can be expected to function without maintenance. For example, some continuous rainfall recorders record on a weekly strip chart and, thus, require weekly visits to remove and replace charts. Other instruments have much larger data storage capabilities and, therefore, require less frequent visits. A balance must be achieved between the frequency of the visits and the resultant quality of the data collected. Too long a time between visits may result in frequent recorder malfunction and, thus, in loss of data, while frequent visits are both time consuming and costly. Various studies have been carried out on the cost-effectiveness and efficiency of data collection. Further details are found in the *Proceedings of the Technical Conference on the Economic and Social Benefits of Meteorological and Hydrological Services* (WMO-No. 733).

The frequency of the visits may also be determined by accuracy requirements of the data. Some data-collection devices may suffer a drift in the relationship between the variable that is recorded and that which the recorded value represents. An example of this is a non-stable stage-discharge relationship. In such cases, visits to the station are required periodically in order to recalibrate the equipment or the measurement equations.

2.5.3.3 New technologies

The introduction of data loggers and telephone/satellite data transmission may have a significant impact on station inspection/data-collection frequencies (2.5.6). However, it should be noted that in order to ensure the quality of the data, regular station maintenance is necessary.

2.5.4 Maintenance of sites

The following maintenance activities should be conducted at data-collection sites at intervals determined to ensure that the quality of the data being recorded is adequate. These activities could be conducted by the observer responsible for the sites, if there is one. However, they should occasionally be performed by an inspector (9.8.4).

All collection sites:

- (a) Service the instruments;
- (b) Replace or upgrade instruments, as required;
- (c) Retrieve or record observations;
- (d) Perform the recommended checks on retrieved records;
- (e) Carry out general checks of all equipment, for example, transmission lines;
- (f) Check and maintain the site to the recommended specifications;
- (g) Check and maintain access to the station;
- (h) Record, in note form, all of the above activities;
- (i) Comment on changes in land use or vegetation;
- (j) Clear debris and overgrowth from all parts of the installation.

Streamflow collection sites:

- (a) Check the bank stability, as necessary;
- (b) Check the level and condition of gauge boards, as necessary;
- (c) Check and service the flow-measuring devices (cableways, etc.), as necessary;
- (d) Check and repair control structures, as necessary;
- (e) Regularly survey cross-sections and take photographs of major station changes after events or with vegetation or land-use changes;
- (f) Record, in note form, all of the above activities and their results;
- (g) Inspect the area around or upstream of the site, and record any significant land-use or other changes in related hydrological characteristics, such as ice.

Further details are found in the *Manual on Stream Gauging* (WMO-No. 519).

Flood gauging cannot be programmed as part of a routine inspection trip because of the unpredictable

nature of floods. A flood action plan should be established prior to the beginning of the storm season and should include priority sites and types of data required. If flood gaugings are required at a site, the preparations must be made during the preceding dry season so that all is ready during the annual flood season. Additional measures may be required if severe flooding is likely.

Preparations include:

- (a) Upgrade site access (helipad, if necessary);
- (b) Equip a temporary campsite with provisions;
- (c) Store and check gauging equipment;
- (d) Flood-proof instrumentation such as stage recorders.

Following the recession of flood waters, particular attention is required to ensure the safety and security of the data-collection site and to restore normal operation of on-site instrumentation. In some cases redesign and reconstruction of the site will be required. This work should take into account information obtained as a result of the flood.

2.5.5 Observations

At all data-collection sites a value must first be sensed, then encoded or recorded, and finally transmitted. Examples of the components of data collection are displayed in Table I.2.9.

2.5.5.1 Manual stations

At the very minimum, observers should be equipped with field notebooks and/or station journals in which the original observations are recorded as they are taken. Forms should also be provided to permit the observer to report observations daily, weekly, fortnightly, or monthly, as required. The field notebook or station journal should be retained by the observer in case the report is lost in transit.

The report forms should be designed to permit easy copying of the results from the field notebook or station journal. A good approach is to have the report form identical to a page in the notebook or journal. At least, the various elements should be in the same columns or rows in both. Space should be allowed in the journal and, perhaps, in the report form for any conversions or corrections that may have to be applied to the original readings.

Alternatively, an observation notebook with carbon paper between successive sheets will permit easy preparation of an original form for dispatch to the central office and a copy for the local station record. This is not a satisfactory procedure where the

notebook is to be carried into the field as moisture can easily make the entries illegible. The report forms may also be coding forms suitable for direct conversion to computer medium.

The value of data can be greatly enhanced – or devalued – by the standard of the accompanying documentation. Observers should be encouraged to comment on any external influences that may affect observations, whether they be related to equipment, exposure, or short-term influence. In addition, input formats and forms should be flexible enough both to allow comments to be appended and for these comments to be accessible with the final data. It is important that published comments be expressed in standard terminology, and it is preferable that correct vocabulary be employed in the field report.

There is also reason for setting up the processing system so that quality coding or tagging is carried out as the observations are made. This is particularly applicable to manual observations because it encourages the making of judgements while the

conditions are being observed. Data from field measurement books may be processed using optical readers or portable field computers that will allow the direct input of observations into computer storage. Such devices allow for reduced data transfer errors and automatic data quality checks.

Field observations that may assist in interpreting water quality should be entered on the report. These observations may include unusual colour or odour of the water, excessive algal growth, oil slicks, surface films, or heavy fish kills. Such observations may prompt the field investigator to take additional observation-based samples, in addition to those required by the routine schedule. The types of samples and their preservation should be consistent with the types of analysis that the investigator thinks is warranted by the prevailing conditions. If additional samples are collected at sites other than the established station, the description of their locations should be recorded accurately. This kind of information and the additional samples may prove very useful in the interpretive phase of the study.

Table I.2.9. The components of data collection

<i>Data collection</i>			
<i>Data capture</i>		<i>Transmission</i>	
<i>Sensing</i>	<i>Recording</i>		
1. Visual Water-level gauge, land use, site description, soil texture, etc.	1. Field notebook Text descriptions and element or parameter values	1. Manual Field observers Postal services Telephone	
2. Mechanical Raingauge, thermometer, current meter, soil penetrometer, water level gauge	2. Field data sheet Purpose designed for particular text descriptions and element or parameter values May be pre-coded for subsequent computer input purposes	2. Automatic (Telemetry) Telephone Dedicated landline Radio Satellite Internet Mobile phone networks	
3. Electrical Thermistor, radiometer, pressure transducer, conductivity probe, encoder	3. Charts Strip charts with element value continuously recorded by pen tracing 4. Computer compatible media (a) Manually recorded Mark sense forms Multiple choice forms (b) Automatically recorded Solid state memory		

Note: The table applies to elements or parameters observed in the field. There are notable groups of data, for example, in soils and water quality, where laboratory analysis or physical samples are performed. Here the data-collection system almost invariably is:

- (a) Mechanical sampling
- (b) Notebook/data sheet field entries.

2.5.5.2 Recording stations

At automatic recording stations, observations are recorded in digital or graphical form. However, the following observations should be recorded at the time of any visits for data retrieval or station maintenance:

- (a) Site identification number;
- (b) Observations from independent sources at the time of collection, for example, gauge boards and storage rainfall gauges;
- (c) Specific comments relating to the recording device, including its status, current observation and time.

Each inspection should be recorded by completing a station-inspection sheet. Data may be recorded in solid-state memory or perforated tape. Final extraction of observations from the recorded data may be performed at computing facilities when removable memory or perforated tape has been used as the recording medium. However, portable computers may be used to extract data directly from data loggers and to verify the data before leaving the station. Field verification allows any necessary repairs or other changes to be made before leaving the site.

Data loggers record data at specific time intervals (as programmed by the user). Intelligent loggers will also allow for data compaction and variability of observation times. In the case of the observation of multiparameters, the coordination of observations can also be performed by the intelligent field logger. For example, rainfall data can be recorded at a five-minute interval or at every tip of a bucket, for stage data when the level alters by more than 1 cm, and water-quality parameters when stream height alters by 10 cm and/or on a 24-hour basis.

With graphical recorders, observations are collected continuously and processing of the data in the office is required. Comments should be written on the chart or noted on the inspection sheet if any errors are detected. As with digital recorders, independent field observations should be made and recorded during each site visit.

After a station has been in operation for a reasonable period, the frequency and timing of inspections should be re-assessed in the light of the capabilities of the instrumentation and the requirements for data at that site. In some cases, consideration should be given to the real-time collection of data via various communications options as a cheaper method of data collection than regular site visits (2.5.6).

2.5.5.3 Real-time reporting

There are many recording and non-recording stations from which real-time data are required, for example, in the operation of reservoirs, flood-warning and forecasting situations, and in some instances as a cost-effective method of data collection.

Real-time data collected by field observers must be reported using a transmission facility, such as a radio or the public telephone system, to the agency. Similarly, recording stations must report via some transmission facility. Recording devices may have the advantage of being able both to transmit data at prescribed intervals/parameter changes and be interrogated by the collecting agency to determine the current situation or reset observation intervals. Data loggers may also provide information on the current available storage capacity of the logger and the condition of the available power supply. Automated quality-control processes can be developed in these situations.

2.5.5.4 Instructions for observers

Clearly written instructions must be provided to all observers. These should contain guidance and directions on the following matters:

- (a) A brief description of instruments, with diagrams;
- (b) Routine care and maintenance of instruments and actions to be taken in the event of serious breakage or malfunctioning;
- (c) Procedures for taking observations;
- (d) Times of routine observations;
- (e) Criteria for the beginning, ending and frequency of special non-routine observations, for example, river-stage observations while water level is above a predetermined height;
- (f) Procedures for making time checks and putting check observations on charts at stations with recording instruments;
- (g) Completion of field notebooks or station journals;
- (h) Completion of report forms, including methods of calculating means and totals with appropriate examples;
- (i) Sending of reports to the central office;
- (j) Special routines for real-time stations.

Such written instructions should be supplemented by oral instructions by the inspector to the observer at the time of installation of instruments and at regular intervals thereafter.

The instructions should emphasize the importance of regular observations with perhaps a brief

account of how the observed data are used in water resources development, hydrological forecasting, or flood-control studies. Any special observations that may be required during special periods, for example, during floods, or any special reports that are to be filed, should be specifically discussed. Observers should be urged not to forget to fill in the spaces for station names, dates and their signature. The necessity of reporting immediately any instrument failure or significant modification of the observing site should be emphasized.

Observers at stations equipped with automatic recording instruments must be provided with instructions on the method of verifying the operation of digital recorders, changing charts and taking check observations. These instructions must stress the importance of annotating the chart with all information that might be required for later processing. This would include station identification, time on, time off, check-gauge readings and any other entries that would make the record more easily interpreted at a later time.

At stations with full-time personnel, the staff should be sufficiently well trained to abstract data from recording instruments. For such stations, carefully worded instructions on the method of abstracting data and on the completion of report forms must be provided. However, at many ordinary stations, where observers may not be thoroughly trained, it may be undesirable to require observers to undertake the relatively complex job of data abstraction. In such cases, digital or graphical records should be forwarded to a central office for processing of the data.

2.5.6 Transmission systems

2.5.6.1 General

During recent years, the demands from users of hydrological data have become more and more complex; therefore, systems that include automatic transmission of hydrological observations have been incorporated into national networks. This has also led to the need for developing codes to facilitate the formatting of observations for the transmission and dissemination of forecasts. Hydrological codes are discussed in 2.3.2. The following describes different possibilities for transmission systems:

- (a) Manual – The observer at the station mails data or initiates radio or telephone calls to the central office on pre-arranged criteria;
- (b) Manual/semi-automatic – The central office manually interrogates the remote automatic

station by telephone, Internet, radio or radio telephone or satellite, and receives single discrete values as often as interrogated. It is possible to have automatic telephone-dialing equipment in the central office that can make calls in series;

- (c) Automatic timed – Automatic equipment at stations is programmed to initiate transmission of a single, instantaneous observation and/or past observations held in a storage register;
- (d) Automatic event indicator – The station transmits automatically, by radio, telephone, Internet or satellite, a specified unit of change of a variable, for example, each centimetre change in the stage of a river;
- (e) Automatic – Data are transmitted by the station and recorded at the central office on a continuous basis.

2.5.6.2 Transmission links

The possible choices of transmission links include:

- (a) Dedicated land-lines – These are used where relatively short distances are involved and commercial lines are not readily available;
- (b) Commercial telephone and telegraph lines – Telephone and telegraph systems can be used whenever feasible. Equipment that permits unattended reception of observations at the central office is available. Measurements and commands can be transmitted to and from the remote site;
- (c) Commercial cellular telephone networks – The ever growing coverage of these networks, together with better and more reliable equipment, make them an interesting and less expensive option for moving data from a site and into the central office. The combination of reliability and low cost makes it more realistic to collect data from stations with no real-time interest, from sites previously considered as somewhat remote, to be transmitted using commercial facilities. Cellular systems can be used in the same way as standard telephone lines and may continue to operate during an extreme event when telephone lines fail;
- (d) Direct radio links – These must be used when requirements cannot be met by those facilities provided by landlines, or when distances or natural obstacles prevent the economic installation of wires. Distances of several to hundreds of kilometres may be spanned by radio transmitters, depending upon the carrier frequency and the transmitter power. At the higher frequencies, the transmitter and receiver must have a clear line-of-sight transmission path. This limits the range without repeater

- stations to about 50 km. In all cases, the installation and operation of radio transmission links are subject to national and international regulations;
- (e) Satellite links – Data transmission using satellites can take place in two ways: transmission of data, as observed by sensors in the satellite (such as imagery) or the use of the satellite to relay data observed at remote ground stations to central receiving locations. At the present time, the science of observation and transmission or retransmission from satellites is developing rapidly. The data involved are available either directly from the spacecraft or through central data banks;
- (f) The Internet – Internet Protocol communication in various forms, including the use of mobile phone networks, makes this an interesting and less expensive way to send data, especially if there is much data to transfer or continuous transfer is wanted. Internet communication works on a number of different physical communication paths, including both mobile and ordinary telephone networks. This makes it more reliable. In systems with a large number of sites, it also makes the retrieval time shorter and the communication system in the main office much easier.

2.5.6.3 Factors affecting the choice of transmission systems

When considering the possibility of including automatic transmission of data in any measuring system, consideration should be given to the following:

- (a) Speed with which data are required. This depends upon the following factors:
- (i) The speed with which changes in the measured variable take place;
 - (ii) The time between the observation and receipt of the data by conventional means, versus automatic transmission systems;
 - (iii) The urgency of having this information available for warnings or forecasts;
 - (iv) The benefits of forecasts from telemetered data and economic losses due to lack or delay of forecasts;
 - (v) The advantages of radio and satellite transmission versus landlines in times of storms and floods when these disasters can destroy the more conventional means of telecommunications at the time that the information is most urgently needed;
- (b) Accessibility of the measurement sites for quality control and maintenance;
- (c) Reliability of the recording device. When local climatic conditions are rigorous, the operation

of on-site mechanical equipment is difficult. Under these situations, it may be more reliable to transmit data electronically to a central climate-controlled office. This system also permits a continuous check of the operation of the sensors;

- (d) Staffing for operational, maintenance and logistic problems. It is important for these aspects to be considered in the planning process and to recognize that each individual project will have its own particularities. Careful attention should be given to the costs and benefits of all the alternatives before any final decision is made. When designing a system for the automatic transmission of data, the main components to consider for staffing purposes are:
- (i) Sensors and encoding equipment;
 - (ii) The transmission links;
 - (iii) Receiving and decoding equipment.

It is necessary to consider these components jointly in the design stage. This is essential because the special characteristics of any one component can have serious consequences on decisions regarding the others. If the ultimate use of the data transmission system is intended for forecasting, then sensing, transmitting and receiving hydrometeorological data is an essential but insufficient component of the forecast system. A forecast centre having personnel who are well-trained in preparing forecasts and warnings, and in notifying persons at risk is also fundamental (United Nations, 2004).

2.5.7 Water-quality monitoring

Chapter 7 provides details of instrumentation and field practices for the collection of water-quality data. The sampling locations, the sampling times, the parameter identifications and the corresponding values must be recorded and coherence must be maintained throughout the handling of the data. If any one of these essential items is lacking, then the whole effort is wasted.

2.5.7.1 Station identification

The importance of an accurate written description of each station location and the conditions under which the samples are collected are discussed in detail in 2.5.2.2.

2.5.7.2 Field sheets for water-quality monitoring

Perhaps one of the most important steps in a sampling programme is the recording on the field sheets of observations, sampling date, time, location

and the measurements made. All field records must be completed before leaving a station. Additional instructions are contained in 2.5.5.

Two examples of a systematic format for recording field analyses and observations are provided in Figures I.2.13 and I.2.14. The formats shown in these figures are appropriate for those personnel that use computer systems for storing their results. The format of Figure I.2.13 can be used by anyone collecting water-quality data. Both formats can be adapted to fit situations specific to a particular need. The following information is usually recorded:

- (a) Sampling site and date;
- (b) Field-measured parameters;
- (c) Instrument calibration;
- (d) Sampling apparatus used and procedures;

- (e) Quality control measures used;
- (f) General remarks and field observations.

2.5.7.3 Transportation of water-quality samples

Once collected, some water samples must be transported to the laboratory. The mode of transportation will depend on the geographic location and the maximum permissible time lapse before analysis for each constituent. The field investigator is responsible for delivering the samples to the airline, bus, train or postal terminal on schedule so that there will be minimal delay in sample transport. Logistics for sample transport and storage should be determined before fieldwork is initiated.
